PUBLIC VERSION

Brinda Westbrook-Sedgwick
Commission Secretary
Public Service Commission
of the District of Columbia
1325 G Street, N.W., Suite 800
Washington, D.C. 20005

Re: Formal Case No. 1176, In the Matter of the Application of Potomac Electric Power Company for Authority to Implement a Multiyear Rate Plan for Electric Distribution Service in the District of Columbia

Dear Ms. Westbrook-Sedgwick:

Enclosed for filing in the above-referenced proceeding, pursuant to the procedural schedule outlined by the Commission, please find the public copy of the *Office of the People's Counsel for the District of Columbia's Direct Testimony of OPC Witnesses, Exhibits OPC (A) – (E).* Below is a list of the Office's witnesses:

OPC Exhibit (A) – David A. Dismukes
OPC Exhibit (B) – Michael P. Gorman
OPC Exhibit (C) – Christopher C. Walters
OPC Exhibit (D) – Brian C. Andrews
OPC Exhibit (E) – Kevin J. Mara

Additionally, OPC Witness Kevin Mara's confidential testimony filing and Witness David E. Dismukes's confidential exhibits will be filed under a separate cover. If there are any questions regarding this matter, please contact Ankush Nayar at 202.727.3071.

Sincerely,

/s/ Sandra Mattavous-Frye
Sandra Mattavous-Frye

I. INTRODUCTION

Q. PLEASE STATE YOUR FULL NAME, ADDRESS, AND OCCUPATION.

A. My name is David E. Dismukes. My business address is 5800 One Perkins Place, Suite 5-F, Baton Rouge, Louisiana, 70808. I am a Consulting Economist with the Acadian Consulting Group ("ACG"), a research and consulting firm that specializes in the analysis of regulatory, economic, financial, accounting, statistical, and public policy issues associated with regulated and energy industries. ACG is a Louisiana-registered partnership, formed in 1995, which is located in Baton Rouge, Louisiana.

Q. WHAT IS YOUR EDUCATIONAL AND PROFESSIONAL BACKGROUND?

A. I hold M.S. and Ph.D. degrees in Economics from Florida State University. Over a career stretching more than three decades, I have been actively involved in research, government service, and consulting. My professional experience includes examination of economic, statistical, and public policy issues in energy and regulated industries. I previously served as a full Professor, Executive Director, and Director of Policy Analysis at the Center for Energy Studies at Louisiana State University ("LSU"). I was also a tenured Professor in the Department of Environmental Sciences and the Director of the Coastal Marine Institute in the College of the Coast and Environment at LSU. I also served as a member of the graduate research faculty at LSU directing and participating in M.S. theses and Ph.D. dissertation committees. On January 13, 2023, I retired from my active positions at LSU but continue to be involved in academic circles serving as a Professor Emeritus at LSU. I also serve on the program faculty and as a Senior Fellow at the Institute of Public Utilities at the Michigan State University teaching energy and regulatory professionals. Exhibit

OPC (A)-1 is my academic vitae, which includes a list of the proceedings in which I have testified, a list of all my publications, presentations, pre-filed expert witness testimony in other jurisdictions, expert reports, expert legislative testimony, and affidavits.

Q. PLEASE SUMMARIZE THE PURPOSE OF YOUR DIRECT TESTIMONY.

A. I have been retained by the Office of the People's Counsel ("OPC") to provide policy and technical analysis on the general issue of whether the Commission should continue to consider a move away from traditional ratemaking in favor of alternative forms of ratemaking ("AFORs"). More specifically, I was retained to analyze the Potomac Electric Power Company ("Pepco," or the "Company") assessment of the Multiyear Rate Plan Pilot ("MRP Pilot") that was approved in Formal Case No. 1156, and the merits of the Company's proposed Multiyear Rate Plan ("MYP") proposal in this case. I also provide an expert opinion regarding Pepco's proposed rate increase for the District of Columbia ("District"). My testimony will provide an overview OPC's case-in-chief and policy positions and will introduce each of OPC's expert witnesses and providing an overview of their testimony and recommendations. My testimony will also specifically address elements of the Company's proposed MYP, traditional test year filing ("TTYF") revenue distribution, and rate design. I will also address growing concerns regarding the affordability of rates in the District, and the Company's Bill Stabilization Adjustment ("BSA").

Q. HAVE YOU PREVIOUSLY TESTIFIED BEFORE THE DISTRICT OF COLUMBIA PUBLIC SERVICE COMMISSION?

A. Yes and those are provided in Exhibit OPC (A)-1.

Q. WERE YOUR TESTIMONY AND EXHIBITS PREPARED BY YOU OR UNDER YOUR DIRECT SUPERVISION AND CONTROL?

A. Yes

Q. HOW IS THE REMAINDER OF YOUR TESTIMONY ORGANIZED?

A. The remainder of my testimony is organized into the following sections:

- Section II: Scope and Summary of Testimony
- Section III: General Concerns Regarding Pepco's Application
- Section IV: Affordability Concerns in the District
- Section V: Revenue Distribution
- Section VI: Rate Design
- Section VII: Pepco's MYP Extension Request
- Section VIII: Bill Stabilization Adjustment
- Section IX: Conclusions and Recommendations

II. SCOPE AND SUMMARY OF TESTIMONY

A. Introduction of OPC Witnesses

Q. PLEASE INTRODUCE OPC'S EXPERT WITNESSES AND SUMMARIZE THE TOPICS OF THEIR RESPECTIVE TESTIMONIES.

A. In addition to my testimony, OPC is sponsoring the testimony of six additional expert witnesses in this proceeding, including:

- **Mr. Michael P. Gorman**, a managing principal of Brubacher & Associates, Inc., presents testimony in OPC Exhibit (B) regarding the Company's' overall revenue requirements for both its traditional rate year proposal and MYP proposal. Mr. Gorman recommends a number of adjustments to the Company's revenue requirements that are based on his own analyses, as well as supporting analyses provided by other OPC experts on such subjects as rate of return, depreciation, and capital spending.

- **Mr. Christopher C. Walters**, an associate with Brubacher & Associates, Inc., presents testimony in OPC Exhibit (C) related to Pepco's requested rate of return. Mr. Walters reviews and analyzes the regulatory utility industry's access to capital, credit rating trends and outlooks, as well as the overall trend in the authorized return on equity for utilities across the country.
- **Mr. Brian C. Andrews**, an associate with Brubacher & Associates, Inc., presents testimony in OPC Exhibit (D) assessing the propriety of, and recommending changes to Pepco's depreciation rates.
- **Mr. Kevin Mara**, an executive vice president at GDS Associates, presents testimony in OPC Exhibit (E) regarding Pepco's proposed construction and capital investment plans and related proposed test-year adjustments for Pepco's "traditional" rate filing and its proposed MYP. Mr. Mara also discusses a number of challenges associated with Pepco's new load forecasting and how the Company's forecasting methods impact capital spending. Finally, Mr. Mara reviews Pepco's proposed use of battery energy storage systems to delay capacity upgrades.

B. Overview of OPC's Positions and Recommendations

Q. PLEASE SUMMARIZE OPC'S CONCERNS AND RECOMMENDATIONS RELATED TO PEPCO'S TRADITIONAL TEST YEAR REVENUE REQUIREMENT PROPOSAL.

A. OPC witness Gorman finds that Pepco's traditional test year revenue deficiency of $108.2 million is overstated by $74.6 million and should, instead, be set at $33.6 million. Mr. Gorman's proposed reductions to Pepco's traditional test year revenue requirement are comprised of $20.0 million associated with a lower proposed return on equity, $40.9 million reduction to depreciation expense, a $10.3 million reduction attributable to Pepco's BSA deferral, and an assortment of additional reductions, including adjustments related to annualized revenues, deferred income taxes, regulatory asset amortization, and inflation.

Q. PLEASE SUMMARIZE OPC'S CONCERNS AND RECOMMENDATIONS RELATED TO PEPCO'S PROPOSED MYP REVENUE REQUIREMENT.

A. OPC witness Gorman finds that Pepco has overstated its proposed MYP revenue requirement by $76.1 million in 2024, $83.6 million in 2025, and $90.8 million in 2026. Mr. Gorman's proposed MYP revenue requirement reductions include:

- Cost of capital related reductions of $25 million to MRP Year 1; $26.8 million to MRP Year 2; and $28.3 million to MRP Year 3.
- Depreciation expense reductions of $46.8 million in 2024, $50 million in 2025, and $52.7 million in 2026.
- A variety of other revenue requirement reductions related to Pepco's sales forecast, service company cost escalation, deferred income taxes, and regulatory asset amortization.

Q. PLEASE SUMMARIZE OPC'S CONCERNS AND RECOMMENDATIONS RELATED TO PEPCO'S PROPOSED COST OF CAPITAL.

A. OPC witness Walters concludes that the recent trend in the authorized return on equity ("ROE") for regulated utilities has declined and remains below 10 percent recently. Mr.

Walters estimates that the current fair market ROE for Pepco is within the range of 9.20 percent to 9.90 percent and recommends the Commission adopt an ROE no greater than the midpoint of 9.55 percent under a traditional test year scenario without the BSA decoupling mechanism. Alternatively, in the event the Commission authorizes Pepco to continue under an MYP, with or without the BSA decoupling mechanism, then OPC witness Walters finds that a range of 9.20 percent to 9.55 percent is more appropriate and recommends the Commission authorize a ROE of no more than the mid-point of 9.30 percent. In addition, Mr. Walters concludes that Pepco's proposed 50 percent equity ratio (excluding short-term debt) significantly exceeds those observed for the proxy group used to estimate Pepco's cost of equity. Mr. Walters does not propose an adjustment to the capital structure but does incorporate the differences in financial risk among proxy group companies into consideration in making his recommendation.

Q. PLEASE SUMMARIZE OPC'S CONCERNS AND RECOMMENDATIONS RELATED TO PEPCO'S PROPOSED CLIMATE-RELATED CAPITAL SPENDING.

A. OPC witness Mara observes that over 90 percent of the projects identified as part of Pepco's "climate ready grid" modernization initiative are nothing more than routine reliability projects that any prudent utility would undertake. Based on this observation, Mr. Mara identifies a number of projects that could be delayed or eliminated without thwarting the District's climate goals.

Q. PLEASE SUMMARIZE OPC'S CONCERNS AND RECOMMENDATIONS RELATED TO PEPCO'S LOAD FORECASTING METHODOLOGIES.

A. OPC witness Mara finds that Pepco's proposed MYP capital budget is overstated and does not reflect the lower load growth suggested by the Company's new load forecasting methodologies. Mr. Mara notes that Pepco's new load forecasting methodologies suggest a slowdown in construction and energy use in the District, resulting in lower capital investment requirements. The lower load growth forecast leads Mr. Mara to recommend a delay in a number of proposed MYP capital projects that need to be removed from the proposed MYP test year including: (1) $635,610 associated with a fifth transformer at the Waterfront substation; (2) $6.1 million associated with two projects aimed at expanding capacity at the Alabama substation; (3) $6.3 million attributable to a battery energy storage system ("BESS") at the Alabama substation; and (4) a $4.5 million BESS-related investment at the Mt. Vernon substation.

Q. PLEASE SUMMARIZE OPC'S CONCERNS AND RECOMMENDATIONS RELATED TO PEPCO'S ALLOCATION OF SUB-TRANSMISSION COSTS.

A. OPC witness Mara an adjustment to account for Pepco's incorrect allocation of the costs of certain sub-transmission projects to the District. Mr. Mara also observes that Pepco has significantly changed its Downtown Resupply Project in its MRP proposal, resulting in a budget increase from $667 million to approximately $1.4 billion. OPC witness Mara finds that this increase is not justified and recommends a number of sub-projects related to the Downtown Resupply Project be eliminated from Pepco's MRP capital budget.

Q. PLEASE SUMMARIZE OPC'S CONCERNS AND RECOMMENDATIONS RELATED TO PEPCO'S DEPRECIATION EXPENSE CALCULATION.

A. OPC witness Andrews finds that Pepco's proposed depreciation expense amount is excessive. OPC witness Andrews challenges a number of Pepco proposed changes that will inflate net salvage values including (1) the Company's proposal to lengthen the average service life of nine plant accounts, (2) its proposal to reduce net salvage value for Account 362 by 30 percent; and (3) its proposal to use a uniform 2.5 percent inflation rate to discount future net salvage costs. Mr. Andrews recommends the Commission reduce the depreciation expense for the MYP by $46.8 million in 2024, $50.0 million in 2025, and $52.7 million in 2026, and that Pepco's proposed traditional test year depreciation expense should be reduced by $40.9 million.

C. Summary of Revenue Requirement, Rate Design and Regulatory Policy Recommendations

Q. WHAT ARE YOUR REVENUE DISTRIBUTION RECOMMENDATIONS?

A. I recommend that the Commission reject the Company's proposed revenue distribution allocation, which places a disproportionate amount of the rate increase on residential customers. Rate classes such as the residential class would see a rate increase of 2.3 times that of the system average. While the Commission has expressed a desire to address negative rates of return for the residential customer class, it has chosen to do so utilizing a policy of gradualism. Moreover, disproportionately allocating rate increases to residential ratepayers as Pepco proposes, has not proven effective in improving the overall rate of return for the residential class. I recommend that the Commission adopt a more reasonable revenue distribution allocation method that limits revenue increases to customer classes currently earning a relative rate of return (RROR) below 0.90 an increase equal to 1.25

times the overall system average increase in order to meet rate gradualism goals and to support electricity cost affordability in the District.

Q. WHAT ARE YOUR CUSTOMER CHARGE RECOMMENDATIONS AND CONCLUSIONS?

A. I recommend that the Commission keep customer charge at their current levels. The Company's customer charges are already on the high side of other regional utilities and do not need to be increased any further. Additionally, residential customers have seen significant cumulative increases in customer charges over the past few rate cases.

Q. WHAT ARE YOUR CONCLUSIONS REGARDING THE COMPANY'S PROPOSED MYP?

A. I recommend that the Commission reject the Company's requested MYP for multiple reasons. First, there has been no review of the previous MRP Pilot that the Commission approved in Formal Case No. 1156. As such, nothing in Pepco's pre-filed testimony or exhibits supports the conclusion that the pilot was successful and resulted in meaningful and measurable ratepayer benefits. Second, in Order No. 20737 (Formal Case No. 1156), the Commission established the framework by which it will review MYP proposals, and explained that it "will determine on a case-by-case basis whether the principles of the framework have been met in the proposed [alternative forms of ratemaking, i.e., AFOR] under the specific facts and circumstances of the case."[1] The Company has not provided sufficient evidence or analysis under this framework demonstrating that the MYP proposal

---

1 *Formal Case No. 1156, In the Matter of the Application of Potomac Electric Power Company for Authority to Implement a Multiyear Rate Plan for Electric Distribution Service in the District of Columbia ("Formal Case No. 1156")*, Order No. 20737, ¶ 96, rel. December 20, 2019.

will provide any net public benefits or to be in the public interest. I will also discuss general concerns with multiyear plans such as the one proposed by Pepco and the fact that the Company fails to demonstrate the need for this form of regulation at this time.

Q. WHAT ARE YOUR RECOMMENDATIONS REGARDING THE COMPANY'S LOW-INCOME PROPOSALS AND ENERGY AFFORDABILITY IN THE DISTRICT?

A. I recommend that the Commission not approve the Company's proposed changes to its low-income programs at the current time and, instead, open a proceeding after the conclusion of the current rate case to examine low-income and affordability issues in a more holistic fashion. Changes to the Company's low-income programs could have important and potentially unintended consequences that affect other District-sponsored programs and other stakeholder initiatives.

Q. WHAT ARE YOUR RECOMMENDATIONS REGARDING THE COMPANY'S BSA?

A. I recommend the BSA be discontinued for several reasons: It is not fulfilling its original purpose and reduces incentives for prudent management by the Company. If the Commission approves some form of a multiyear rate plan, then this only further justifies discontinuing the BSA, as elements of the BSA are redundant of a multiyear rate plan. Finally, in the current energy transition environment, revenue decoupling's purpose is at odds with decarbonization and electrification.

Q. DO YOU HAVE AN ALTERNATIVE RECOMMENDATION IF THE COMMISSION DECIDES TO RETAIN THE BSA?

A. Yes. If for any reason the Commission decides to retain the BSA, I recommend adoption of the Company's proposed BSA modifications.

Q. WHAT IS YOUR RECOMMENDATION REGARDING THE COMPANY'S PROPOSED RATE BASE TREATMENT OF BSA DEFERRED BALANCES?

A. I recommend the Commission reject the Company's proposal to include its test year BSA deferred balance as an element of rate base, allowing the Company to earn a rate of return on this balance. Even ignoring the Company's admitted billing determinant error, which has contributed to the significant growth in these deferred balances over the past few years, the Commission should recognize that the Company had the opportunity to request changes to the BSA operations at any point in the mechanism's 14-year history. Accepting the Company's request to include BSA deferred balances as part of rate base now would effectively reward Pepco for not exercising prudent oversight of BSA operations.

Q. WHAT EVIDENCE HAS PEPCO PROVIDED TO SUPPORT A FINDING THAT IT HAS PRUDENTLY ADMINISTERED THE BSA?

A. None. Pepco does not provide any analysis to demonstrate that its administration of the BSA was prudent.

Q. DO YOU HAVE A RECOMMENDATION REGARDING THE CURRENT LARGE BSA DEFERRAL BALANCES FOR COMMERCIAL RATE CLASSES?

A. Yes. I recommend the Commission disallow the Company from recovering the portion of BSA deferral balances, associated with the Company's past administrative errors, from retail customers. Pepco has provided no analysis or evidence to support a finding of fact that it prudently operated the BSA despite the billing determinant error. The BSA mechanism should not function to immunize the Company from its own operational and business mistakes. I recommend the Commission remove $42.2 million of BSA deferral balance from ratepayer recovery, including $19.3 million from the Time Metered General Service-Low Voltage ("GTLV") rate class and $20.1 million from the Time Metered General Service-Low Voltage ("MGTLV") rate class. This removal is to account for the Company's previous acknowledged billing determinant mistake in Formal Case No. 1150 and its faulty GTLV normalization adjustment in the same proceeding.

Q. DO YOU HAVE ANY RECOMMENDATIONS REGARDING THE REGULATORY TREATMENT OF PANDEMIC-RELATED LOST REVENUES?

A. Yes. I recommend that the Commission consider alternative recovery options for pandemic related BSA deferral balance outside of the BSA such as mechanism already established by the Commission for recovery of pandemic-related expenses.

III. GENERAL CONCERNS REGARDING PEPCO'S APPLICATION

Q. PLEASE SUMMARIZE PEPCO'S RATE REQUEST.

A. On April 13, 2023, Pepco filed a request for approval of its MYP .[2] This follows a previous MRP Pilot approved on a pilot basis (called by Pepco at the time as a "Modified Enhanced Multiyear Rate Plan), by the Commission in 2021.[3] The currently proposed MYP will increase distribution revenues by $190.7 million over a three-year period starting February

---

[2] *Formal Case No. 1176*, Application of Potomac Electric Power Company, p. 5, filed April 13, 2023 ("Application").

[3] *Formal Case No. 1156*, Order No. 20755, ¶ 142, rel. June 8, 2021.

15, 2024,[4] including $81.5 million (43 percent) to residential customers.[5] This proposed increase represented a 34.7 percent increase in system-wide distribution revenues, or an 80.0 percent increase in residential distribution revenues.[6]

Q. HAS THE COMMISSION MADE ANY RULINGS ON THE SUCCESSES, OR FAILURES OF THE CURRENTLY ACTIVE PILOT MYP?

A No. In adopting the MRP Pilot, the Commission explained that it would review the successes and failures of this new regulatory mechanism before considering any renewal or permanent plan.[7] That review did not occur before Pepco submitted its April 13, 2023 Application in Formal Case No. 1176, and I understand OPC is challenging the omission of that process on appeal. For purposes of my testimony, I note that Commission Order No. 21886 directed Pepco to file supplemental testimony explaining in quantitative and qualitative terms the benefits of, problems identified, and lessons learned from the MRP Pilot.[8] Order No. 21886 also directed Pepco to file a traditional one-year rate case with a test year ending December 31, 2023.[9] On August 31, 2023, Pepco filed supplemental testimony pursuant to Order No. 21886.[10] Likewise, on October 16, 2023, Pepco filed a

9 *Id.*

10 *See Formal Case No. 1176*, Exhibit PEPCO (2A), Supplemental Direct Testimony of Elizabeth M. D. O'Donnell.

one-year traditional test year compliance filing ("TTYCF") pursuant to Order No. 21886.[11] This supplemental TTYCF request would increase the Company's annual distribution revenues by $108.2 million, or $46.0 million to residential customers.[12] This represents a 19.8 percent increase in system-wide distribution revenues or a 45.4 percent increase in residential distribution revenues.[13]

Q. HAS THE COMMISSION PREVIOUSLY IDENTIFIED THE COMPLEXITY ASSOCIATED WITH MOVING FROM TRADITIONAL RATEMAKING TO AN MRP-BASED REGULATION?

A. Yes. The Commission recognizes the complexity of moving from traditional regulation to a regulation paradigm based on alternative forms of ratemaking ("AFOR"), noting that such considerations should be "deliberate, paying careful attention to the structure and framework for the evaluation of [alternative forms of regulation] so that unintended operational or financial outcomes are mitigated and managed."[14] The Commission ultimately noted that any move away from traditional ratemaking "may require multiple rate proceedings to fully implement."[15] However, to date, no such proceedings have arisen relative to assessing Pepco's MRP Pilot performance.

15 *Id.*

Q. ARE THERE PRACTICAL DIFFICULTIES IN REVIEWING THE PERFORMANCE OF THE MRP PILOT, THE PROPOSED MYP, AND A TTYCF IN THE SAME PROCEEDING?

A. Yes. The Commission should recognize that each of these three forms of regulatory oversight are complex that, by themselves, generally warrant a proceeding in and of themselves for the Commission and stakeholders to review. In this proceeding alone, Pepco has filed three sets of testimony covering (1) the Company's proposed rate increases under its proposed MYP; (2) the Company's supposed assessment of the MYP Pilot performance; and (3) the Company's proposed rate increases under its proposed TTYCF. Considering all three of these filings simultaneously places strain on the Commission and all stakeholders. Further, the Commission should recognize that there are separate and distinct rate implications for each of these regulatory mechanisms. Consideration of all issues poses difficulties in issuing and responding to discovery, composing pre-filed testimony, and conducting adequate evidentiary cross-examination within the limited timeframe associated with a single proceeding.

Q. DID PEPCO FILE TESTIMONY IN THE CURRENT PROCEEDING EMPIRICALLY ANALYSIS ASSESSING THE HISTORIC PERFORMANCE OF THE MYP RELATIVE TO TRADITIONAL REGULATION?

A. No. While the Company was required to file testimony reviewing the MRP Pilot, it did not quantify any benefits that are directly attributable to its MRP Pilot. More importantly, the Company did not show how the MRP Pilot led to benefits that would not have arisen under the counterfactual regulatory arrangement, which is traditional regulation.

Q. HOW WILL PEPCO'S CURRENT MYP PROPOSAL IMPACT A TYPICAL RESIDENTIAL CUSTOMER?

A. As will be outlined in my testimony further, the MYP proposal will impact residential retail customers, in general, and several subsets of these residential customers, adversely. My testimony will discuss in further detail how the proposal will, in particular, adversely impact energy affordability for some of the District's most vulnerable residential customers. Consider that the Company itself shows that its proposed MYP will result in a first-year typical residential bill increase (assuming 614 kWh/month) of $6.18 per month, or 6.37 percent on a total distribution bill basis.[16] This is over two time the going rate of inflation for normal household goods and services. But this is not the only increase that can be expected by the proposed MYP. Furthermore, the initial "year one" increase will be followed by "year two" and "year three" increases of $6.13 and $6.09 per month, respectively.[17] In total, the Company estimates that the typical residential customer will see monthly bill increases of $18.40 per month over the three-year MYP, or close to 19 percent on a total distribution bill basis.[18]

Q. HOW DOES THE PROPOSED RATE INCREASE FOR RATE YEAR 1 COMPARE TO PAST PEPCO RATE CASES?

A. This rate proceeding continues a long string of substantial rate increase requests made by the Company in the District. What is different about the Company's current MYP proposal

---

16 *Formal Case No. 1176*, Application, at 2.

17 *Id.*

18 *Id.*

(relative to past "traditional regulation") is the considerable increase in rates that will be facilitated by this unnecessary AFOR. Consider that Pepco's proposed first year rate increase ($116.4 million) represents a 21.2 percent increase in rates. Figure 1, provided below, shows that, in total dollar terms, the Company's proposed one-year increase in this proceeding ($116.4 million) is nearly as large as the sum of the Commission-approved rate increases in the Company's last three rate cases (Formal Case Nos. 1156, 1139, and 1103).[19] Figure 1 illustrates the significance of these rate increases, affirming that the only quantifiable outcome they can expect from the MYP, if approved, is the "rate predictability" of very high electricity bills.

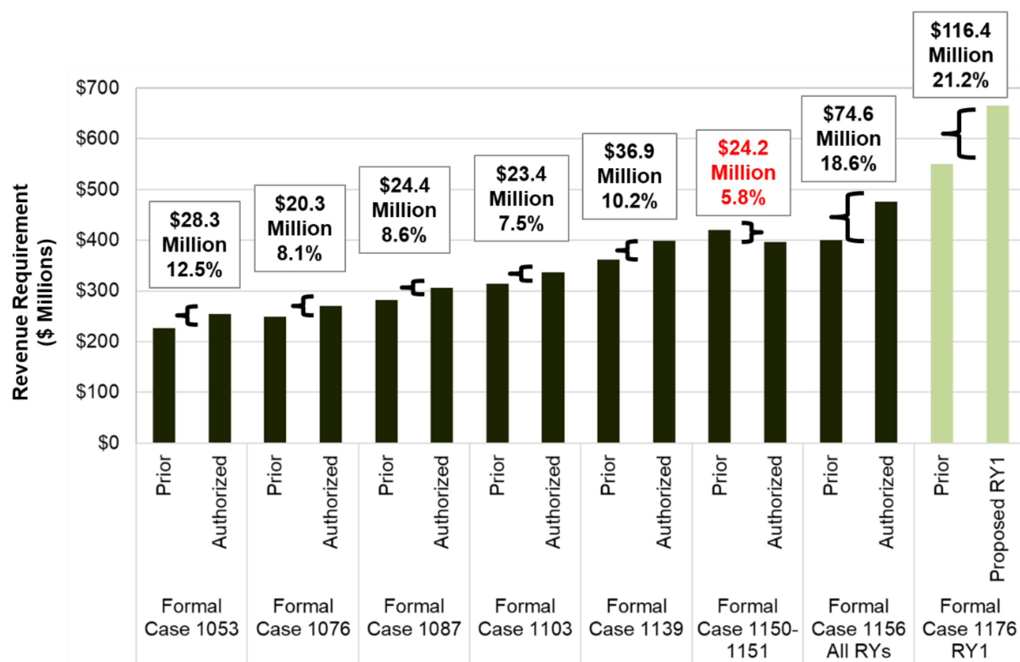

Figure 1: Comparison of Prior Pepco Rate Increases

19 I do not reference Formal Case Nos. 1150 and 1151 given the unique circumstances of those cases surrounding the effect of the Tax Cut and Jobs Act of 2017 ("2017 TCJA").

Q. WHAT HAS BEEN MOTIVATING THESE LARGE RATE INCREASE REQUESTS?

A. In prior cases, the Company claimed that these rate increases were motivated by infrastructure investments designed to improve customer service, system reliability, and customer satisfaction, as well as to advance the forward-focused policy goals of the District.[20] The Company notes that the current rate request is needed to support and advance decarbonization goals in the District through what the Company refers to as its "Climate Ready Grid" initiative.[21]

Q. WHAT ARE THE BIG PICTURE ISSUES INCENTING UTILITIES INTO MAKING SUCH LARGE CAPITAL INVESTMENTS?

A. Energy efficiency initiatives, federally mandated appliance standards, growth in behind-the-meter generation, and state/local building code changes have slowed growth in use per customer ("UPC"). This means that the only way utilities can grow earnings is to expand investments into areas that are either (a) not specific to load growth, or (b) heavily rely upon load growth. These include investments in efficiency, resilience, reliability, resource diversity, and decarbonization.

Q. HOW DO THESE CHANGES IN ENERGY USAGE IMPACT UTILITY COST RECOVERY?

---

20 *See* Exhibit OPC (A)-20, *Formal Case No. 1150, In the Matter of the Application of Potomac Electric Power Company for Authority to Increase Existing Retail Rates and Charges for Electric Distribution Service* ("*Formal Case No. 1150*"), Application of Potomac Electric Power Company at 3, filed December 19, 2017 ("FC 1150 Application"); Exhibit OPC (A)-21, *Formal Case No. 1150*, Exhibit PEPCO (A) (Dismukes) at 6:8-11; Exhibit OPC (A)-22, *Formal Case No. 1139*, Application of Potomac Electric Power Company at 3, filed June 30, 2016 ("FC 1139 Application"); and Exhibit OPC (A)-23, *Formal Case 1156*, Application at 7.

21 *Formal Case No. 1176*, Application, at 4.

A. Utility rates, in very general terms, are set using average costs which, themselves, are simply costs divided by output (or kWhs). If sales (the denominator) fall, then rates have to increase in order to assure cost recovery on both historic and incremental investments. Thus, for utilities like Pepco, increasing investments in non-revenue/non-load growth items like resiliency, reliability and sustainability, coupled with falling sales, results in very large and repetitive rate increases. The only way to stop these rate increases is to (a) reduce or stop capital expenditures and/or (b) grow sales.

Q. BY HOW MUCH WILL DISTRIBUTION RATES INCREASE OVER THE THREE YEAR PERIOD OF THE PROPOSED MYP?

A. Figure 2, provided below, shows that by the end of the MYP period, the Company's base distribution rates will have increased by more than $190.7 million, or by more than 34.7 percent when compared to existing rates over a mere three-year period. Thus, the Company's proposal will only exacerbate the sharp increase in rates that have been charged to District ratepayers.

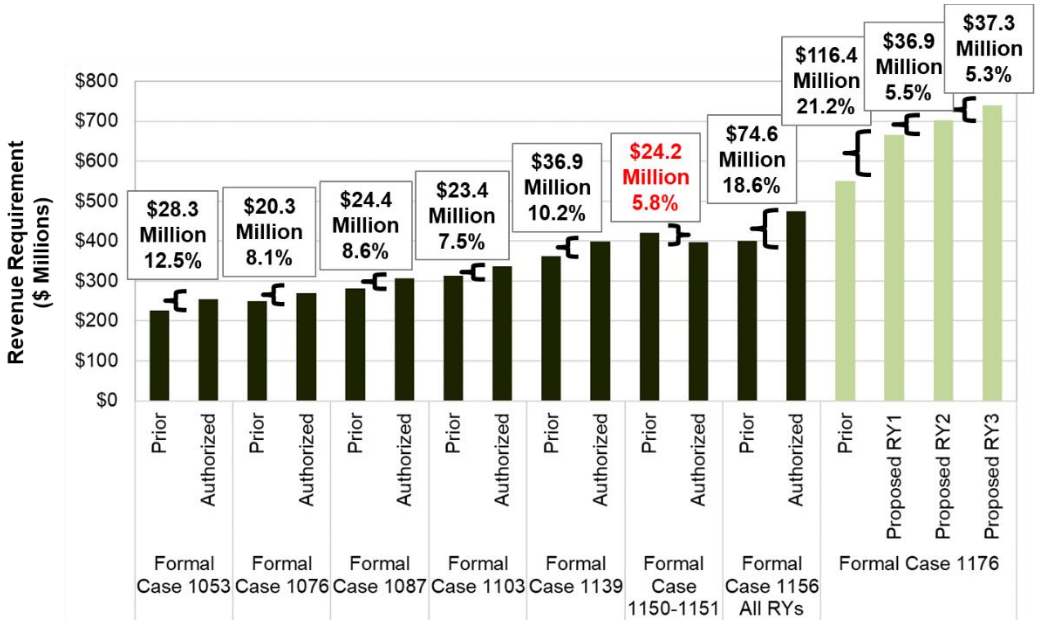

Figure 2: Comparison of Prior Pepco Rate Increases, with MRP

Q. WILL THE PROPOSED MYP PROVIDE RATEPAYERS WITH ANY RELIEF FROM THESE HISTORICALLY LARGE AND CONTINUALLY LARGE RATE INCREASE PROPOSALS?

A. No. Figure 2 shows that the Company's proposed MYP will not alleviate the historic pattern of large rate increases dating back to 2007 (FC 1053). The Company's MYP will not reduce the Company's capital investments, nor will it increase volumetric sales, meaning that this "new" approach to regulation will do nothing more than sustain the "old" trends in consistently large rate increases under an alternative regulatory framework.

Q. IS THERE REASON TO BELIEVE THAT THE COMPANY'S PROPOSED RATE INCREASE IN THIS PROCEEDING IS TOO LARGE?

A. Yes, particularly if past trends have any implication for the rate increase proposals in this proceeding. Figure 3 compares the Company's historic rate increase requests to those allowed by the Commission in its final order. The Commission has consistently contained rate increases to those that are between 42.1 and 60.6 percent of the amount originally requested by Pepco in its past applications. In short, it should be recognized that the efforts of the Commission, OPC, and other parties to carefully scrutinize Pepco's rate case applications have curtailed the Company's excessive rate increase requests.

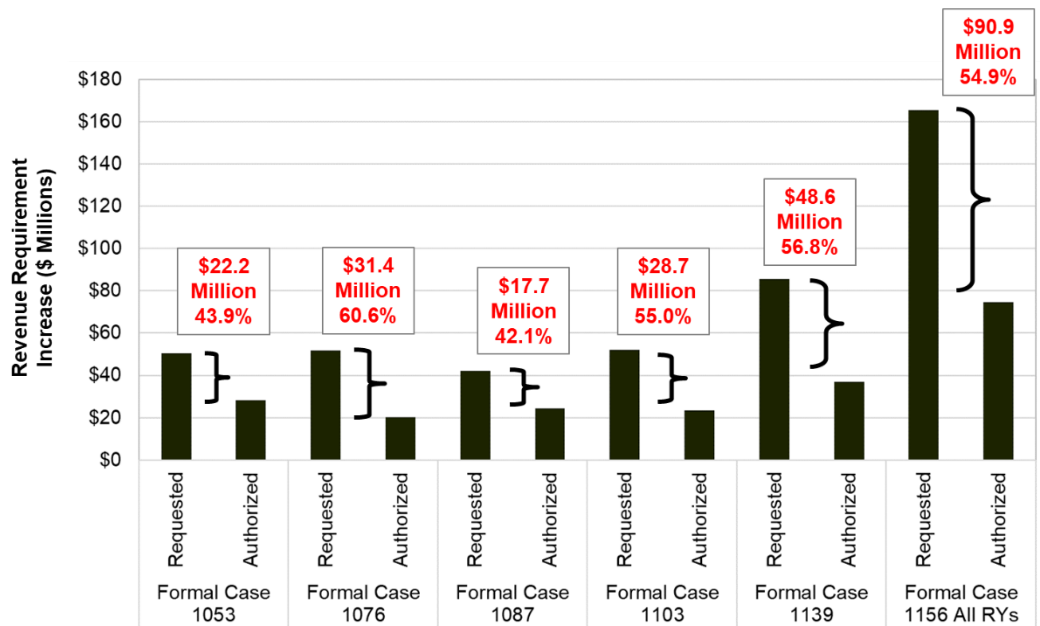

Figure 3: PEPCO Historic Requested to Authorized Revenue Requirements
Note: Formal Case 1150 and 1151 excluded due to effects of 2017 Tax Cuts and Jobs Act.

Q. HOW DOES THE COMPANY PROPOSE TO ALLOCATE ITS PROPOSED RATE INCREASE IN THIS PROCEEDING?

A. The Company proposes a revenue distribution that will increase rates for under-earning classes at a rate that is equal to 2.3, or 230 percent, its overall system-wide rate increase request.[22] This is while the Company proposes a 34.7 percent overall distribution rate

[22] Exhibit PEPCO (E) (Bonikowski) at 11:11-32 and 14:19-22.

increase for all customers during the course of the three-year MYP.[23] This means that the Company's proposal would lead to a substantial rate increase for residential customers of more than 80.0 percent over three years.[24] Again, it is hard to fathom how the proposed MYP will lead to any measurable or quantitative benefits with rate increases of these magnitudes.

Q. IS IT EQUITABLE FOR RESIDENTIAL CUSTOMERS TO BEAR SUCH A DISPROPORTIONATE BURDEN OF THE COMPANY'S PROPOSED RATE INCREASE?

A. No. The Company notes that the current rate request is needed to support and advance decarbonization goals in the District through what the Company refers to as its "Climate Ready Grid" initiative.[25] While the District has climate targets, the Commission has not approved a clear path forward in Formal Case No. 1167, which is the docket examining how utilities will move forward in light of those targets. That proceeding is also considering the Washington Gas and Light Company's ("WGL's") climate proposals, as well as stakeholder input on the plans submitted by both utilities, all of which have yet to be reconciled. Furthermore, OPC witness Mara raises serious questions about the nature of the Company's proposed capital investments and provides quantifiable evidence that over 95 percent of these proposed MYP investments are "business as usual" in nature, and cannot be matched to any reductions in greenhouse gas ("GHG") emissions, improve

---

[23] Exhibit PEPCO (E)-3.

[24] Exhibit PEPCO (E)-1.

[25] *Formal Case No. 1176*, Application, at 4.

energy end use efficiencies, nor any operating or cost efficiencies that could translate into future rate reductions.

Q. IF THESE MYP INVESTMENTS PROVIDING SYSTEM-WIDE BENEFITS, AS SUGGESTED BY PEPCO, SHOULD THEIR COSTS BE PRIMARILY BORN BY RESIDENTIAL CUSTOMERS?

A. No. Even if true, the Company's claims about MYP infrastructure investments resulting in system-wide, even societal, benefits need to be recovered equally across all customer classes, and not disproportionately by any one specific class. However, the Company's revenue distribution proposal completely ignores this fact, placing the majority of the cost burden of these societal investments onto one customer class: residential customers.

Q. WHY IS THE COMPANY PROPOSING DISPROPORTIONATE RATE INCREASES FOR RESIDENTIAL CUSTOMERS?

A. The Company claims that its revenue distribution proposal is based upon the Commission's policy of addressing historical disparities in rate class-specific rates of return.[26] This policy was first established in Formal Case No. 1076, filed in May of 2009, more than a decade ago.[27] Since that time, residential customers have disproportionately borne the burden of the Company's proposed rate increases in the majority of subsequent rate filings. Yet, despite these disproportionate increases, there has been no improvement in these historic cross-subsidies until the current filing. Importantly, however, this recent improvement in

---

26 Exhibit PEPCO (E) (Bonikowski) at 10:4-11.

27 *Formal Case No. 1076, In the Matter of the Application of Potomac Electric Power Company for Authority to Increase Existing Retail Rates and Charges for Electric Distribution Service* ("*Formal Case No. 1076*"), Application of Potomac Electric Power Company ("1076 Application").

supposed rate disparities was accomplished after residential customers were assigned a lower-than-average rate increase in the Company's prior rate case filing in Formal Case No. 1156.

Q. HAVE YOU COMPARED THESE TRENDS IN RESIDENTIAL RATE INCREASES TO ANY OTHER METRICS?

A. Yes. Figure 4 compares the historic rate of growth in residential distribution rates to the overall rate of inflation in consumer goods as measured by the Consumer Price Index for Urban Consumers ("CPI-U"). This analysis shows that since September 2007, residential distribution rates have increased at nearly 2.4 times the rate of inflation. The increase in base rates is significantly more than increases in other consumer expenses.

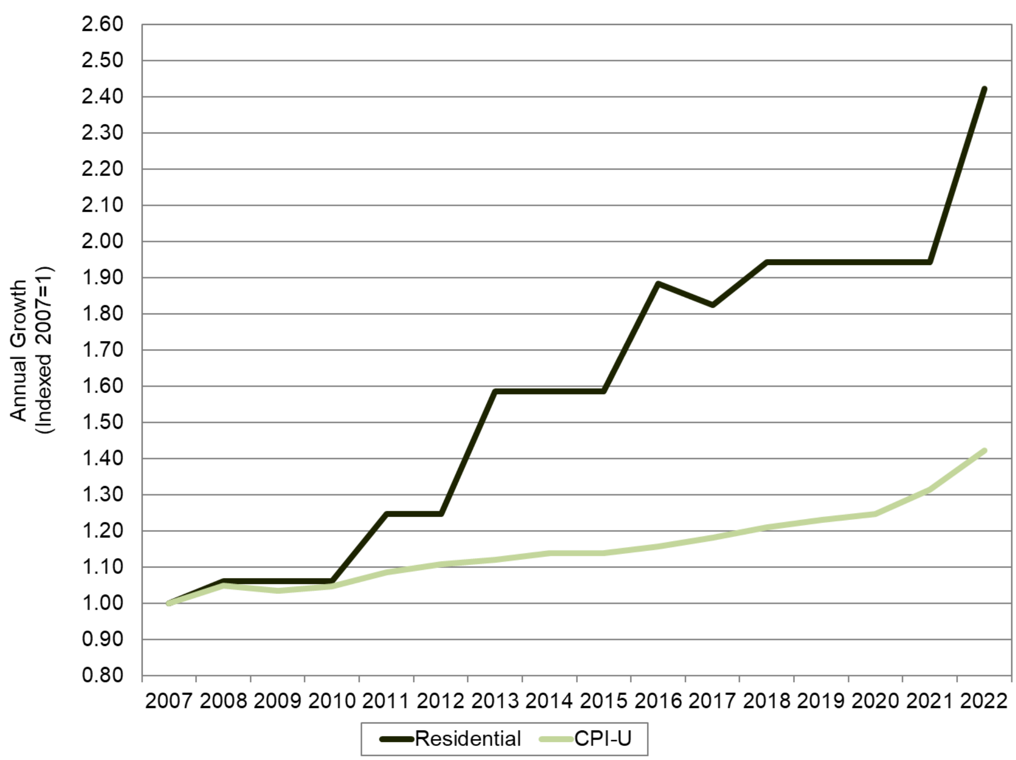

Figure 4: Residential Base Rate Growth to Consumer Price Index-Urban (CPI-U)

Q. WHY HAS THE POLICY OF DISPROPORTIONATE RATE INCREASES FOR RESIDENTIAL CUSTOMERS NOT ACCOMPLISHED THE STATED GOAL OF REMOVING HISTORIC CROSS-SUBSIDIES BETWEEN CUSTOMER CLASSES?

A. The Company's proposed capital expenditures, and the rate increases that support these investments, surpass any rate-rebalancing these prior revenue distribution policies could accomplish. In other words, the Commission's policy goals that support the Company's non-revenue generating investment proposals are in direct conflict with its goals to rebalance rates. This is only going to get worse, not better if the Commission approves the Company's MYP. I cannot envision a way in which the Commission can continue to support the level of MYP investments proposed by the Company and correct its long-standing ratemaking challenges at the same time. The more important of these two competing policy initiatives must be chosen, holding the other in abeyance until such time that the need for continued reliability, resiliency and sustainability investments have dissipated.

IV. <u>AFFORDABILITY</u>

Q. HOW DO YOU DEFINE ENERGY AFFORDABILITY?

A. Energy affordability reflects a fundamental household value proposition: it defines how expensive energy is relative to a household's income. Affordability, more generally, can be utilized as an index number to measure, among other things, the ability of a specific type of household to pay for essential utility services such as water, electric, and/or natural gas.

Q. ARE THERE ANY THRESHOLDS AT WHICH ENERGY SIMPLY BECOMES "UNAFFORDABLE" OR "BURDENSOME?"

A. Yes. The most accepted and utilized threshold at which utilities, and thus energy, becomes unaffordable or burdensome is when the percentage of income spent on energy exceeds six percent.[28] This threshold comes from the Fisher, Sheehan, and Colton's Home Energy Affordability Gap Study from 2011. The threshold is based on the premise that total shelter costs (including rent/mortgage and all utilities) should not exceed 30 percent of income, and that 20 percent of shelter costs should be allocated to energy bills. Thus, 20 percent of 30 percent yields a six percent affordable utility burden.[29] Utility burdens below six percent are classified as "affordable" and energy burdens above six percent are classified as "unaffordable".

Q. HOW DOES ACADEMIC LITERATURE EXAMINE UTILITY AFFORDABILITY?

A. The academic literature examines energy affordability through various metrics, but predominantly through utility and energy burden rates. Utility burden rates measure the impact of a utility bill on household income. The American Council for an Energy Efficient Economy (ACEEE)'s *Understanding Energy Affordability* Report best encapsulates what the academic literature has studied. Their report determines four drivers of high energy burdens: (1) physical (i.e. housing age and type, poor insulation, weather extremes); (2)

---

[28] *See*, "Understanding Energy Affordability" ACEEE, 2015, page 2.

[29] Fisher, Sheehan, and Colton. "Home Energy Affordability in New York: The Affordability Gap 2008-2010", June 2011, page 2.

economic (i.e. chronic or sudden economic hardship); (3) behavioral (lack of access to information for bill payment assistance); and (4) policy (insufficient programs for bill assistance, high fixed customer charges).[30] It also examines utility burden rates throughout the United States, classifying any total utility burden above six percent as a household that experiences high energy burden.[31]

Q HOW IS THE CONCEPT OF ENERGY AFFORDABILITY RECOGNIZED IN REGULATION AND PUBLIC POLICY?

A. Energy affordability is increasingly becoming an important issue in regulatory policy with various states and local governments setting energy affordability targets. Recently, New York set a state-wide goal of achieving six percent energy burden.[32] Portland released a Ten-Year Plan to Reduce Energy Burden in Oregon Affordable Housing.[33] Adopting a three-phase process, the California Public Utilities Commission ("CPUC") developed the state's first energy affordability metric that tracks affordability for essential service level (electric, gas, water, and communications).[34] During the first phase, the CPUC defined affordability and established an affordability framework, setting residential household utility essential service levels and adopting the following three metrics to assess affordability of essential utility services: Affordability Ratio, Hours-at-Minimum-Wage,

---

34 California Public Utilities Commission Order 18-07-006, 2018.

and Socioeconomic Vulnerability Index.[35] In phase two, the CPUC focuses on implementation of the affordability framework through various efforts including rate cases, grants, and program assessments, while in the third phase of the order, the CPUC focuses on analyzing strategies to mitigate future rate increases based on the affordability metrics calculated.[36] On the other hand, the Pennsylvania Public Utility Commission ("PPUC") examined home energy burdens for low-income Pennsylvanians in its Home Energy Affordability 2019 report,[37] and subsequently issued a policy statement on March 21, 2020, establishing maximum energy burdens for customers.[38] The study found a wide disparity in the average percent of household income spent on natural gas and electric services by Customer Assistance Programs ("CAP") customers and non-CAP customers. CAP customers with gas heating and electric non-heating had a combined average energy burden of 12 to 14 percent or with electric heat eight to 10 percent.[39] In contrast, non-CAP customers had an average energy burden of six percent for gas heating and electric non-heating or four percent for electric heating.[40] These examples demonstrate that examining energy affordability has become paramount in utility regulation across the country.

Q. WHERE DOES THE DISTRICT OF COLUMBIA RANK NATIONALLY IN TERMS OF INCOME INEQUALITY?

---

35 *Id*.

36 *Id*.

37 Exhibit OPC (A)-24, Home Energy Affordability for Low-Income Customers in Pennsylvania, (January 2019) Pennsylvania Public Utility Commission.

38 52 PA. Code Ch. 69.

39 Exhibit OPC (A)-24, page 109.

40 *Id*.

A. Wealth and income gaps in the District remain stark, with income inequality in the District being amongst the highest in the nation. Over the past decades, the District of Columbia has experienced economic growth, but this growth has been generally uneven.[41] One contributing factor to wealth inequality is the stagnant wages for low-to-moderate income households, while costs such as housing and utilities have increased significantly.[42] According to the U.S. Bureau of Labor Statistics, Consumer Price Index for transportation, food, and housing in the District of Columbia metro increased by 43 percent, 59 percent, and 70 percent respectively over the past 20 years.[43]

Q. IS HOUSING AFFORDABILITY A GROWING CONCERN IN THE DISTRICT?

A. Yes. Housing affordability is a critical issue that the District of Columbia faces. Over the last two decades, the number of affordable housing units has decreased while the number of high-cost housing units has multiplied.[44] In 2002, 40 percent of housing rented for less $800 per month, falling to 20 percent by 2013 and to less than 15 percent by 2021.[45] Moreover, the District of Columbia has the nation’s fourth highest “housing wage”, that is, the hourly wage needed to afford housing.[46] District of Columbia follows Hawaii,

46 Ariel Drehobl, Diana Hernández, Roxana Ayala, and Lauren Ross. “An Examination of District Residents’ Experiences with Utility Burdens and Affordability Programs.” American Council for an Energy-Efficient Economy, March 2021, page 4.

California, and Massachusetts in the "housing wage" ranking.[47] The increase in housing costs has made it difficult for low-income residents to afford basic necessities, even foregoing resources needed for a healthy lifestyle and living in substandard housing.[48]

Q. HAVE HOUSEHOLD ELECTRICITY COSTS RISEN OVER THE PAST TWO DECADES?

A Yes. From 2000 to 2019, the average electric bill for a resident in the District of Columbia increased 78 percent, from $55 to $98 per month.[49] D.C. water bills have also increased significantly over the years.[50] These increases exacerbate financial pressures for low-income residents, leading them to seek assistance. From April 2019 to June 2020 alone, the OPC received over 450 complaints about high water bills, disconnections, and payment disputes. OPC also received 912 complaints for PEPCO, 444 complaints for Washington Gas, and 164 complaints for third-party providers during FY 2019.[51] The significant number of formal complaints filed by residents underscores the severity of utility unaffordability.[52]

Q. HOW HAS ENERGY AFFORDABILITY CHANGED OVER THE PAST SEVERAL YEARS IN THE DISTRICT?

---

[47] *Id*.

[48] *Id*, page 5.

[49] *Id*.

[50] *Id*.

[51] *Id*, page 6.

[52] *Id*.

A. As shown in Exhibit OPC (A)-2, costs associated with essential electric use will have increased 32 percent if the Company's proposed MYP is approved. Residential rate increases have far outpaced inflation at an average rate of nine percent per year since 2007.

Q HOW WOULD THE COMPANY'S MYP IMPACT ENERGY AFFORDABILITY?

A. Exhibit OPC (A)-2 shows that Pepco's rates have continuously exceeded the six percent affordability threshold for the bottom 15 percent of income households in the District since at least 2015. Importantly, this metric includes only natural gas and electric utility expenses and thus only includes a subset of total utility burden (which also includes water, sewer, and telecommunication utility expenses) used in academic literature when examining utility burden. The Company's proposed rate increases through its proposed MYP will only exacerbate this situation with energy expenditures constituting approximately nine percent of these household disposable income by 2026. Exhibit OPC (A)-2 finds that, if approved by the Commission, the Company's proposal will result in unaffordable residential rates for at least the bottom 20 percent of District households, one-fifth of all households in the District.

Q. WHAT RESIDENTIAL CUSTOMER ASSISTANCE PROGRAMS DOES THE COMPANY CURRENTLY OFFER?

A. The Company offers a Residential Aid Discount ("RAD") Program that provides eligible customers with a monthly credit for their full monthly distribution charges.[53] This credit is known as the Residential Aid Credit ("RAC"). To qualify for the RAD Program, customers must apply and receive certification of income eligibility from the District of

53 Direct Testimony of M.J. Bonikowski, page 31, 21-22.

Columbia Department of Energy and the Environment ("DOEE").[54] The RAC, pursuant to Order No. 18059 in Formal Case No. 1120, offsets the amount of the distribution customer charge, distribution energy charge, RAD Surcharge, Sustainable Energy Trust Fund Surcharge, and Energy Assistance Trust Fund Surcharge for RAD participants. In addition to this program, the Arrearage Management Program (AMP) allows qualifying Pepco customers in the District of Columbia the option of reducing or eliminating outstanding balances on residential accounts by making qualifying payments on budget billing one enrolled into the program. To be eligible to participate in the AMP, customers must be enrolled in the RAD Program and have a minimum balance of $300 that is at least 60 days past due and have a balance at or below $3,600.[55]

Q. WHAT OTHER ASSISTANCE PROGRAMS ARE AVAILABLE FOR LOW TO MODERATE INCOME HOUSEHOLDS IN THE COMPANY'S JURISDICTION?

A. There are four energy utility assistance programs administered by DOEE that serves low to moderate income residents in Washington D.C: (1) Low-Income Home Energy Assistance Program (LIHEAP); (2) Utility Discount Program (UDP); (3) Weatherization Assistance Program (WAP); and (4) Solar for All (SFA).[56]

54 *Id*.

55 PEPCO Energy Assistance Website. https://thesource.pepcoholdings.com/what-energy-assistance-options-are-available/#:~:text=In%20addition%20to%20these%20programs,outstanding%20balances%20on%20residential%20accounts.

56 Ariel Drehobl, Diana Hernández, Roxana Ayala, and Lauren Ross. "An Examination of District Residents' Experiences with Utility Burdens and Affordability Programs." American Council for an Energy-Efficient Economy, March 2021, page 1.

Q. WHAT ASSISTANCE DOES THE LOW-INCOME HOME ENERGY ASSISTANCE PROGRAM ("LIHEAP") OFFER?

A. LIHEAP offers a one-time energy bill assistance between $250 and $1,800. The exact discount varies by various factors such as household size, total household income, heating source, and dwelling type.[57] To qualify for LIHEAP, customers need to be at or below 60 percent of the state median income. In fiscal year 2020, LIHEAP had total funding of $14,769,286 and served 9,654 households.[58] The state-eligible population in fiscal year 2020 was 76,602, meaning that LIHEAP served 12 percent of income-eligible households.[59] These numbers show that while important, the federal LIHEAP program has its limitations in addressing the needs of District consumers as it only serves a small percentage of income-eligible households.

Q. WHAT ASSISTANCE DOES THE UTILITY DISCOUNT PROGRAM ("UDP") OFFER?

A. The UDP offers a yearly bill discount of up to $475 on electric bills and $276 for gas heating bills, and/or over $962 on water and sewer bills to low-income District of Columbia residents.[60] To qualify for UDP, there is a maximum annual income limit: $79,700 for a household size of 1, $91,100 for a household size of 2, $102,500 for a household size of 3,

---

57 *Id*.

58 District of Columbia LIHEAP FY2020 State Profile.

59 *Id*.

60 Department of Energy and Environment UDP Homepage

and $113,850 for a household size of 4.[61] These income limits are annually established by the U.S. Department of Health and Human Services.[62]

Q. WHAT ASSISTANCE DOES SOLAR FOR ALL ("SFA") OFFER?

A. SFA seeks to increase access to solar energy for low-income customers. Those who are at or below 80 percent of the state median income are eligible for free installation of PV systems on their home or eligible to participate in community solar.[63] Participants of Solar for All save about $500 per year on their electric bills. 3,103 residents participated in the SFA program in FY 2020.[64]

Q. WHAT ASSISTANCE DOES THE WEATHERIZATION ASSISTANCE PROGRAM ("WAP") OFFER?

A. This program supports customers with weatherization assistance. This assistance includes measures such as insulation, duct sealing, heating and cooling systems repair or replacement, air infiltration mitigation, and ENERGY STAR lighting and appliances, home energy efficiency, lowers bills, and improves home comfort.[65] 297 residents participated in WAP in FY 2020.[66]

Q. WHAT CHANGES IS THE COMPANY PROPOSING TO ITS AMP PROGRAM?

---

[61] *Id*. There are additional income limits for household sizes of 5,6,7, and 8, $125,250, $136,650, $148,050, and $159,400 respectively.

[62] *Id*.

[64] *Id*, page 14.

[65] *Id*, page 1.

[66] *Id*, page 14.

A. The Company proposes to adopt the automatic enrollment feature that the Commission approved for Washington Gas Light Company ("WGL") in Formal Case No. 1164 in Order No. 21536.[67] This means that any RAD customer will be automatically enrolled into AMP if they meet eligibility requirements.[68] By lowering this barrier to entry, the Company hopes to increase accessibility of this assistance program. In addition, consistent with the approach approved for WGL, the Company will notify customers within 15 days of enrollment and these customers will have 45 days to opt out of the program.[69] A customer who fails to complete the program requirements will not be negatively impacted: there will be no retroactive removal for earned AMP credits and the customer will still be able to enter a deferred payment arrangement.[70]

Q. WHAT CHANGES IS THE COMPANY PROPOSING TO ITS RAD PROGRAM?

A. The Company proposes to expand the RAD program through additional marketing and outreach as well as expanding current eligibility requirements.[71] These new eligibility requirements will allow the Company to qualify any customers who has already been qualified by any District of Columbia governmental agency for low-income assistance.[72] In addition, because the AMP requires customers to be enrolled in the RAD program to qualify, AMP enrollment will likely increase of the pool of eligible RAD customers is

70 *Id*.

71 Direct Testimony of Elizabeth O'Donnell, page 19, 5-9.

72 *Id*.

increased.[73] The Company plans to commit to additional marketing and outreach, broader advertising campaigns, and working with third party stakeholders to achieve this goal.[74]

Q. HOW MUCH WILL THE RAD PROGRAM PROPOSAL COST?

A. The Company estimates that the increased outreach effort for its RAD program will cost $900,000.[75] In addition, the Company anticipated an additional incremental cost of $160,000 per year associated with personnel engaged in application processing.[76] With the expected increase in enrollment, the RAD surcharge is likely to increase if the proposed changes are approved by the Commission.[77]

Q. WHAT ARE YOUR RECOMMENDATIONS REGARDING THE COMPANY'S RAD PROPOSAL?

A. I recommend that the Commission not approve the Company's proposal at the current time and, instead, open a proceeding after the conclusion of the current rate case to look at low-income and affordability issues in a more holistic fashion. Changes to the RAD program could have important and potentially unintended consequences that affect other DOEE offered programs and other stakeholder initiatives. A more focused, stand-alone proceeding seems to be the better venue to consider such issues and develop an approach for consistent measurement and monitoring of energy affordability in the District.

[77] *Id*.

V. <u>REVENUE DISTRIBUTION</u>

A. Revenue Distribution Objectives

Q. PLEASE EXPLAIN THE PURPOSE OF THE REVENUE DISTRIBUTION PROCESS IN SETTING RATES.

A. The revenue distribution process allocates a utility's overall revenue deficiency across customer classes, which in turn, is used to establish a new set of retail rates. The revenue distribution process often uses the results from the class cost of service study ("CCOSS") as its starting point but not necessarily as its ending point. Class-specific revenue responsibilities are established by allocating the system-wide revenue deficiency to classes that are under-earning, relative to their estimated rate of return ("ROR"), and assigning, at least in theory, revenue decreases to those classes that are over-earning relative to their CCOSS-estimated class returns. The final class revenue responsibilities are then used, in conjunction with the billing determinants for each class, to determine rates. In summary, the revenue distribution process can be thought of as the initial step taken to establish rates.

Q. DOES THE REVENUE DISTRIBUTION PROCESS INCLUDE ANY POLICY CONSIDERATIONS?

A. Yes. The Commission has discretion in setting class revenue requirements.[78] As is the case in this proceeding, allocating the overall system-wide revenue deficiency entirely on a full cost of service basis can result in a very significant and adverse rate impact for certain under-earning classes. To avoid such a result, regulators often temper the revenue responsibilities assigned to various customer classes in order to meet a set of broad

---

[78] *Formal Case No. 1156*, Order No. 20755, ¶ 388.

ratemaking policy goals. Each of these policy considerations requires consideration of the specific facts of case.

Q. WHAT ARE THE BROADER RATEMAKING POLICY GOALS?

A. There are several generally accepted rate-making principles used in utility regulation that include:

1) Rates should be fair, just, and reasonable, and not unduly discriminatory.
2) To the extent possible, gradualism should be used to protect customers from rate shock.
3) Rate continuity should be maintained.
4) Rates should be informed by costs, but class cost of service results need not be the only factor used in rate development.
5) Rates should be understandable to customers.

Q. HOW ARE THE ABOVE PRINCIPLES APPLIED IN DEVELOPING RATES FOR A REGULATED UTILITY?

A. It is important to consider all of the principles I mentioned above. However, any principle's relative weight can change depending upon the importance of certain policy goals. Rate design should strike a balance between policy goals and resulting rates that are fair, just, and reasonable. There is no pre-set or universally accepted formula for developing rates and, as a result, sound judgment is necessary to formulate a rate design that meets these objectives. And as explained above, the Commission needs to examine the specific facts of a case in applying these principles.

Q. HAS THE COMMISSION MADE SIMILAR FINDINGS AND CONCLUSIONS IN ADDRESSING RATE DESIGN?

A. Yes. The Commission has stated in the past that the appropriate determination of rates is "not a matter for the slide-rule,"[79] and involves judgment regarding a myriad of facts. As part of its inquiry, the Commission considers cost factors and non-cost factors, such as efficiency and a customer's value of service.[80] Within this general framework, the Commission has historically upheld a policy of gradualism in moving rates towards cost-causation.[81] However, the Commission has made it clear that this is a general policy, seeing no requirement of uniformity among class rates of return and that other "equitable considerations" such as value of service and ability to pay, the quality of service delivered, historical rate patterns, the need to conserve energy resources, and other market-place reliability must be also considered by the Commission in establishing just and reasonable rates.[82]

B. Company's Proposed Revenue Distribution

Q. PLEASE EXPLAIN HOW THE COMPANY PROPOSES TO DISTRIBUTE ITS CLASS REVENUE REQUIREMENTS.

A. The Company proposes a four-step revenue allocation methodology in the current proceeding.[83] In step one, the Company identified Schedules GS-3A and TN as rate schedules with unitized rate of return ("UROR"), or relative rate of return (i.e., RROR),

---

79 *See Formal Case No. 1053, In the Matter of the Application of the Potomac Electric Power Company for Authority to Increase Existing Retail Rates and Charges for Electric Distribution Service* ("*Formal Case No. 1053*"), Order No. 14712, ¶ 308, rel. January 30, 2008 (citing *Washington Gas Light Co. v. Pub. Serv. Comm'n. of D.C.*, 450 A.2d 1187, 1206 (D.C. 1982)).

80 *See Formal Case No. 1053*, Order No. 14712, ¶ 308.

81 *See id.*, ¶ 309.

82 *Formal Case No. 1156*, Order No. 20755 ¶ 388.

83 *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 10:4-9.

greater than three times the system average rate of return and excluded these classes from any distribution rate increase.[84] In step two, the Company defines a "steady state" RROR band of plus or minus 0.10 (or 0.90 to 1.10 RROR) to indicate rate classes with RORs relative close to system average rate of return.[85] In step three, the Company assigns rate classes with RRORs of 0.90 or less a distribution revenue increase of 2.3 times the proposed system average increase.[86] In step four, the remaining revenue requirement increase is assigned to remaining rate classes on an equal proportionate basis.[87] Exhibit OPC (A)-3 presents the Company's estimated class rates of return, and its proposed revenue distribution, under its current and proposed rates.

Q. DEFINE THE CONCEPT OF A RELATIVE RATE OF RETURN.

A. The RROR effectively standardizes the class-specific rate of return estimated by a CCOSS to the overall system average. In other words, it divides the estimated class ROR by the estimated system ROR. For instance, assume that the residential class is earning a class-specific eight percent ROR, and further assume that the system-wide average ROR estimated by the same CCOSS is also eight percent. The residential class, in this example, can be said to be earning a 1.0 RROR if the estimated ROR is the same as the overall system (*i.e.*, eight percent divided by eight percent equals 1.0). Put another way, any class earning a 1.0 RROR can be said to be making its full contribution to the system's overall

---

[84] *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 11:2-4, 13:14-20, and 17, Table 3.

[85] *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 11:5-10 and 14:11-16; notably, no rate classes were found by the Company to have current RROR existing within the defined steady state range.

[86] *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 11:11-23 and 14:19-22.

[87] *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 12:1-7.

ROR (*i.e.*, there is no cross-subsidy). A RROR that is greater than 1.0 indicates that a particular class is contributing more than the system average contribution to the Company's overall return. Likewise, a class that earns a RROR less than 1.0 but greater than zero can be said to be making a less-than-average contribution to the overall system.

Q. HOW ARE THE VARIOUS RATE YEAR INCREASES ALLOCATED ACROSS CUSTOMER CLASSES?

A. The Company proposes to allocate each rate year increase on a relative allocation basis, with the total revenue increase assigned to an individual rate class over the proposed MYP being equal to the Company's proposed allocation multiplied by the total proposed MYP incremental revenue requirement increase.[88] For example, the Company proposes that Schedule MGT LV be allocated 22.92 percent of all its MYP revenue increases.[89] Thus, Schedule MGT LV customers will be assigned 22.92 percent of any individual rate year increase. However, the exception to this proposal is Schedule R customers wherein the Company proposes spread the total proposed MYP allocated revenue requirement increase equally across all three rate years on an equal monetary basis.[90] This will result in roughly a $27 million annual increase to Schedule R customers each year across the full duration of the proposed MYP.[91]

---

[88] *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 20:11-19.

[89] *Formal Case No. 1176*, Exhibit PEPCO (E)-2

[90] *Formal Case No. 1176*, Exhibit PEPCO (E)-3.

[91] *Formal Case No. 1176*, Exhibit PEPCO (E)-3.

Q. DOES THE COMPANY'S TTYCF PROPOSED REVENUE ALLOCATION DIFFER FROM ITS PROPOSED ALLOCATION UNDER THE PROPOSED MYP?

A. Yes, slightly. The Company proposes to allocate 42.52 percent of its proposed TTYCF rate increase to residential customers,[92] compared to the proposed 42.73 percent under its proposed MYP.[93] However, these differences are solely due to the Company's proposed lower overall requested base revenue increase in its TTYCF ($63.7 million),[94] compared with its requested first year increase under the proposed MYP ($67.9 million),[95] and not any difference in proposed revenue allocation process.

Q. DO YOU AGREE THAT A CLASS RROR LESS THAN ONE IS PROBLEMATIC OR INEQUITABLE?

A. Not necessarily. Consistent with the principles identified above, there may be factual or policy reasons to support such a result that does not result in an inequitable cross-subsidization. For example, the presence and/or continuation of a RROR below 1.0 could be the result of a prior agreed-upon rate freeze that prevents class rates from increasing to correct the revenue deficiency (relative to cost of service). In this example, the presence of a RROR below 1.0 is simply a function of a prior policy decision, not necessarily the result of some arbitrary or intentionally designed inequity. Nonetheless, I understand the

95 *Formal Case No. 1176*, Exhibit PEPCO (E)-2.

Commission has a stated goal of ending negative class RORs over a series of Pepco rate cases.

Q. HOW DOES THE COMPANY PROPOSE TO INCREASE RATES FOR ITS UNDER-EARNING CLASSES?

A. The Company proposes a revenue distribution that will increase rates for classes earning less than 0.90 RRORs that is equal to 2.3 times the overall system-wide percentage increase.[96] The Company is also proposing to increase rates at a system-wide average of 34.8 percent in order to recover its estimated revenue deficiency.[97] Thus, the Company's proposal for classes with RRORs of less than 0.9 will see rate increases that are, in absolute percentage terms, approximately 80 percent (i.e., 2.3 times 34.7 percent) across the full term of the proposed MYP.[98] Exhibit OPC (A)-4 presents a summary of the Company's proposed total rate increase by rate schedule for the entirety of the proposed MYP.

Q. WHAT HAVE BEEN THE COMMISSION'S PAST POLICIES REGARDING RESIDENTIAL CLASS NEGATIVE RELATIVE RETURNS?

A. The Commission has stated that it is committed to "moving in a deliberate and reasonable fashion to eliminate negative class RORs."[99] It first recognized the issue in Formal Case Nos. 1087 and 1103. The Commission began taking corrective action to eliminate disparities in customer class RORs in Formal Case No. 1103, assigning $11.11 million, or

98 *Id.*

99 *Formal Case No. 1103*, *In the Matter of the Application of the Potomac Electric Power Company for Authority to Increase Existing Retail Rates and Charges for Electric Distribution Service* ("*Formal Case No. 1103*"), Order No. 17424 ¶ 437, rel. March 26, 2014.

47 percent of the proposed jurisdictional increase, to the residential class.[100] Nothing in its policy, however, requires completely eliminating all such disparities within the context of a single rate case.[101]

Q. DID THE COMMISSION REINFORCE A POLICY PREFERENCE FOR ADDRESSING THE NEGATIVE RROR FOR THE RESIDENTIAL CLASSES IN SUBSEQUENT RATE CASES?

A. Yes, to an extent. In Formal Case No. 1139, the Commission reiterated that it has historically had a policy of gradually lessening the disparities in RRORs between rate classes.[102] However, the Commission noted that there is no requirement of uniformity among ROR from different customer classes, and that equity considerations such as value of service and ability to pay, among others, may be considered in setting both customer class revenue requirements and in determining appropriate rate design.[103] These are factual questions the Commission must consider in evaluating application of its general policy.

Q. HOW DID THE COMMISSION ALLOCATE THE RATE INCREASE TO THE RESIDENTIAL RATE CLASS IN THE COMPANY'S LAST RATE CASE, FORMAL CASE NO. 1156?

A. Given the uncertainty associated with potential impacts of the pandemic on the local economy, the Commission decided to adopt a more uniform revenue allocation across rate

---

100 *Id.*

101 *Id.* at ¶ 438.

102 *See Formal Case No. 1139*, Order No. 18846, ¶ 453.

103 *Id*.

classes, with residential and SL-E customers receiving rate increases approximately equal to 0.89 times the system average increase.[104] In approving a less than system average increase the Commission noted that it recognized that the approved revenue allocation "only marginally address[ed] the commercial class's subsidization of the residential class's costs."[105]

Q. WILL PEPCO'S PROPOSAL SUCCEED IN ELIMINATING NEGATIVE CLASS RORS?

A. No, it is not likely that these negative class returns will be eliminated. I have examined the historic trends in the Company's allowed revenue distribution, and those trends show that over the several years the Commission has allocated a greater than average share of the Company's past rate increases to the residential rate classes, the residential class's RROR did not improve. Indeed, the only improvement in the residential classes' RROR occurred after the Company's most recent rate case filing. Exhibit OPC (A)-5 examines the Commission's authorized revenue allocations across customer classes, going back to Formal Case No. 1053 decided in 2007, more than a decade ago. In the subsequent three rate cases Formal Case Nos. 1076, 1087, and 1103, the Commission approved increases to base rates for residential customers that were between 2.21 and 2.48 times the system average rate increases. In other words, residential base rate increases for these classes were more than double the rate increases that were approved at the overall system level. Yet,

---

[104] *Formal Case No. 1156*, Order No. 20755, ¶ 394.

[105] *Id.*, ¶ 395.

these disproportionate, larger-than-average rate increases did not improve the estimated RRORs for the residential classes.

Q. PLEASE EXPLAIN.

A. Exhibit OPC (A)-5 shows that in Formal Case No. 1076, the first rate case in which the Commission articulated its policy of eliminating negative RRORs, the total residential customer class was estimated to be earning a RROR of -0.47. Later, in Formal Case No. 1087, the estimated RROR decreased to -0.54 despite the fact that residential customers were assessed with a rate increase that was 2.21 times the system average. In the following rate case (Formal Case No. 1103), residential customers were estimated to be earning a RROR of -0.41. While this RROR increased slightly from the prior rate case, this moderate change in the RROR was paid for with a disproportionately large rate increase that was 2.48 times the overall system average. Subsequent cases continued this trend, with the Company reporting residential RRORs that were worse than previous years, despite the fact that the residential class received a rate increase consistent with the system average rate increase in Formal Case No. 1139, and received a disproportionately small rate decrease in the Company’s last rate case that incorporated operating savings due to the passage of the 2017 TCJA, namely Formal Case Nos. 1150/1151. .

Q. HAS THE RESIDENTIAL RROR IMPROVED RECENTLY?

A. Yes. In Formal Case No. 1156, the Company estimated that residential customers were earning a RROR of -1.00. However, in the current proceeding the Company estimates that earnings from residential customers has improved to a RROR of -0.68. This represents an approximate one-third reduction in negative RROR for residential customers since the

Company's last rate case. Rather than "only marginally address[ing] the commercial class' subsidization of the residential class' costs,"[106] as stated by the Commission in its Order, the Commission's approval of a less than average rate increase for residential customer has led to the most substantial improvement in class subsidization since at least Formal Case No. 1053.

Q. HAVE YOU CONDUCTED ANY OTHER ANALYSES THAT EXAMINE THE HISTORIC TRENDS IN THE COMPANY'S ALLOWED REVENUES ON A PER CUSTOMER CLASS BASIS?

A. Yes, I have provided this analysis in Exhibit OPC (A)-6. This analysis examines a number of different ratemaking statistics, on a per customer class basis, dating back to Formal Case No. 1053. I have analyzed statistics including number of customers, energy sales, revenues, and revenues per kWh sold. The analysis clearly shows that the total residential class has received allowed revenue increases of 189.3 percent over the past 17 years compared to the 137.5 percent for other commercial classes. If the Company's proposed rate case is approved as filed, residential customers will have seen rate increases of **402.2 percent** since Formal Case No. 1053. Compare this to the other customer classes, over a comparable time period, that will have only seen a 195.2 percent increase. The residential classes' combined per kWh revenue has grown from $0.0178 per kWh in 2006 (Formal Case No. 1053) to $0.0432 per kWh, and if the Company's current proposals are accepted in their entirety in this rate case, will grow to $0.0748 per kWh by 2025. Thus, continuing a policy of saddling residential customers with exceptionally large rate increases, in hopes

[106] *Formal Case No. 1156*, Order No. 20755, ¶ 395.

of solving what appears to be some kind of systemic rate design problem, appears to be fruitless.

Q. WHY WON'T THE COMPANY'S PROPOSED REVENUE DISTRIBUTION RESOLVE THE NEGATIVE RROR PROBLEM?

A. The Company's revenue distribution proposal will not resolve the problem because it is based upon a static, and not dynamic view, of the Company's cost trends and CCOSS results. The results of the analysis I described above suggest that costs historically were simply increasing at rates faster than those that could be reasonably allocated to residential customers.

Q. HOW SHOULD THE COMMISSION RECONCILE ITS GOAL OF ELIMINATING NEGATIVE CLASS RORS WITH THE FACT THAT RATES ARE INCREASING FASTER THAN WHAT CAN BE REASONABLY ASSIGNED TO RESIDENTIAL CUSTOMERS?

A. These goals cannot be reconciled. Therefore, I recommend that the Commission re-consider its policy of assigning relatively higher portions of any revenue increase in an attempt to eliminate negative RRORs at this time given the facts of this case and the experience from recent rate cases. I cannot envision a way in which the Commission can financially support the Company's efforts to improve reliability or other policy directives in the District at the current rate of spending and correct its long-standing ratemaking challenges at the same time. If the Commission does not adopt my recommendation, it should explain to the District's ratepayers how these two policy objectives can be met simultaneously and why they should be confident that circumstances will be different this time in light of the experience in recent rate cases.

C. Revenue Distribution Recommendations

Q. DOES THE COMPANY'S PROPOSED REVENUE DISTRIBUTION DIFFER FROM THAT PROPOSED BY THE COMPANY IN PRIOR RATE CASES?

A. Yes. In Formal Case No. 1139, the Company proposed to allocate revenues to the main residential classes[107] by one third of the difference between these customer classes' then-current respective rates of return and a zero percent rate of return.[108] In this manner, the Company stated that it would move the ROR for the main residential classes to a zero percent ROR over three successive rate cases.[109]

Q. DID THE COMMISSION APPROVE THE COMPANY'S PROPOSED REVENUE DISTRIBUTION APPROACH IN FORMAL CASE NO. 1139?

A. No. While the Commission did accept the Company's proposal to allocate $7.45 million of the approved $36.888 million increase to the residential class, it importantly rejected the Company's proposed three-step plan.[110] In its decision, the Commission found that increasing residential rates by the amount thought to be needed to eliminate the estimated negative RRORs over the course of two or three cases would result in rate increases that could potentially lead to rate shock.[111]

---

[107] Residential ("R") and Residential-All Electric ("R-AE") classes. These tariff classes have been merged for Cost of Service purposes in the current proceeding as simply the "R" customer class.

[108] *See Formal Case No. 1139*, Exhibit PEPCO (G) (Janocha) at 4:20-22.

[109] *Id*. at 7:6-9.

[110] *See Formal Case No. 1139*, Order No. 18846, ¶ 455.

[111] *Id*., ¶ 456.

> We make this revenue requirement allocation recognizing that adopting Pepco's 20% residential allocation marginally impacts the commercial class' subsidization of the residential class' costs. We are reducing Pepco's total request by 52% and providing a corresponding bill reduction to the estimated $3.84 residential bill increase Pepco estimated in its Application, resulting in a $209 average increase to residents. Further, we have decided not to move as aggressively towards reducing the negative rate of return as we have in the past or as AOBA has suggested. If we moved to reduce the commercial class subsidization of residential class customers so that residential RORs reach zero in two or three rate cases, the rate impact in this proceeding would have been $6.46 per month (for two rate cases) or $4.32 (for three rate cases). Therefore, Pepco's rate increase is being distributed among the customer classes in a manner that continues to *gradually* adjust rate structures so that rates move closer to being cost-based for all customer classes while minimizing rate shock in this proceeding.[112]

Q. IS THE COMPANY'S PROPOSED REVENUE DISTRIBUTION CONSISTENT WITH ITS RECOMMENDATIONS IN PAST RATE CASES?

A. Yes. While the Company does not state in its current application or testimony that it is proposing to increase rates to under-earning classes by an amount thought to be needed to eliminate current negative RRORs over a series of cases, the Company's proposal appears to be designed around a similar intention. As shown in Exhibit OPC (A)-3, the Company finds that residential customers would require an additional $161.6 million in allocated revenue requirement in order to eliminate existing negative earnings to the customer class. The Company's proposed revenue distribution would increase residential customer rates by $27.2 million per year for each year of the proposed MYP, or $54.3 million within the first two years of the MYP. Effectively, the Company is continuing to advocate for its

---

112 *Id*.

failed previous proposals of increasing rates to under-earning rate classes by an amount thought to be needed to eliminate the estimated negative RRORs over the course of multiple cases. The only difference in the current proceeding is the Company's use of its proposed MRP as a singular conduit for this proposal since the MRP includes three separate rate increases over a three-year time period.

Q. WHAT IS YOUR RECOMMENDATION REGARDING THE COMPANY'S PROPOSED REVENUE DISTRIBUTION?

A. I recommend that the Company's proposed revenue distribution allocating an increase of 2.3 times the system average for customer classes currently earning RROR less than 0.90 be rejected. In place of the Company's proposal, I recommend that the Commission adopt a more reasonable revenue distribution allocation method that assigns customer classes currently earning RROR lower than 0.90 a revenue increase equal to 1.25 times the overall system average increase. High allocations of any rate increase onto under-earning rate classes, as proposed by Pepco, should not be approved until the Commission can be assured that any enhanced residential revenue responsibility allocation will lead to an improvement in its estimated RROR. Over the past several years, the Commission has allocated a significant share of the Company's requested rate increase to the residential classes, and, despite those increases, the residential classes' RRORs have not improved. There is no reason to assume that pursuing the same revenue distribution strategy in this rate case will result in any differing results, and it is likely that the Commission will not be successful in addressing this RROR challenge until such time that the Company's infrastructure investment growth slows.

Q. HAVE YOU PREPARED A SUMMARY OF THE EFFECTS OF YOUR PROPOSED REVENUE DISTRIBUTION?

A. Yes. My proposed alternative revenue distribution is presented in Exhibit OPC (A)-7. My proposed revenue distribution would lower the proposed increase in base rates to residential customers to 15.5 percent, compared to the Company's proposed increase to these same customers of 28.53 percent.

VI. RATE DESIGN

A. Rate Design Objectives

Q. WHAT ARE THE COMPANY'S RATE DESIGN GOALS?

A. The Company states that the guiding principles used in the development of its distribution rate design reflect the directives given by the Commission in Formal Case Nos. 1139, 1103, 1087, 1076, and 1156.[113] Specifically, the Company finds that past Commission rulings have presented a position that the Commission desires rates to have a greater emphasis on customer charges and demand rates, and less emphasis on volumetric charges.[114]

Q. HOW SHOULD POLICY BALANCE RATE DESIGN GOALS BETWEEN SETTING APPROPRIATE CUSTOMER CHARGES AND VOLUMETRIC RATES?

A. Modern utility pricing theory is primarily concerned with the development of optimal tariff design, which over the years has become dominated by a form of pricing referred to as a "two-part tariff," sometimes referred to more technically as a non-linear (or non-uniform)

---

113 *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 23:19-21.

114 *Id.* at 23:21-24:3.

pricing approach. Once a class revenue requirement is established, the goal for regulators should be one that sets the most appropriate rates based upon various efficiency and equity considerations. Balancing the weight of how costs are recovered between fixed rates, variable rates, block rates, and seasonal rates are all integrated parts of that process.

Q. WHAT IS THE APPROPRIATE ROLE OF COSTS IN SETTING RATES BASED UPON A TWO-PART TARIFF?

A. Costs can be instructive in establishing a baseline upon which prices may be set, but costs do not need to serve as the sole or exclusive basis for rates in order for them to be set optimally (i.e., fixed charges do not need to strictly equal fixed costs, variable rates need not strictly equal variable costs). Unfortunately, repeated discussions regarding the "fixed charge-equals-fixed cost" philosophy can often drown out meaningful discussions about other equally important considerations in setting rates in imperfect markets. In fact, appropriate rate setting in the context of a two-part tariff typically has more to do with consumer demand than it does with cost.

B. Customer Charge Proposals

Q. PLEASE DISCUSS THE COMPANY'S RESIDENTIAL CUSTOMER CHARGE PROPOSAL.

A. A summary of the Company's current and proposed customer charges under both its proposed MYP and TTYCF are provided in Exhibit OPC (A)-8. The Company proposes to increase the residential customer charge by $1.00 in each rate year (RY1, RY2, and RY3).[115] Collectively, such changes represent a $3.00 increase from the current residential

[115] *Id.* at 31:7-8.

customer charge of $16.09, and would, in effect, raise existing customer charges by 18.6 percent. In its TTYCF request, the Company proposes to immediately increase the residential customer charge by $2.76, or 17.2 percent. As can be seen in Exhibit OPC (A)-8, the Company's proposed changes to customer charges in its TTYCF approximate its proposed changes in its MYP .

Q. IS THE COMPANY PROPOSING TO INCREASE ANY OTHER CLASS' CUSTOMER CHARGES?

A. Yes. I identify those increases in Exhibit OPC (A)-8. In summary, the Company is proposing the following customer charge increases by RY3:[116]

- An increase in customer charge for its General Service - Secondary ("GS ND") class of 16.4 percent.
- An increase in customer charge for its General Service - Temporal ("T") class of 16.4 percent.
- An increase in customer charge for its Time Metered General Service - Low Voltage ("GT LV") class of 60.9 percent.
- An increase in customer charge for its Time Metered General Service - Primary ("GT 3A") class of 21.0 percent.
- An increase in customer charge for its Rapid Transit Service ("RT") class of 23.2 percent.

Q. IS THE COMPANY PROPOSING TO DECREASE THE CUSTOMER CHARGES OF ANY OF ITS RATE CLASSES?

A. Yes. Pepco is proposing to decrease the customer charge for its Master Metered Apartments ("MMA") class from $5.44 to $1.78, or by approximately 67.3 percent.[117] The Company is also proposing to reduce the monthly customer charge for the General Service

---

116 *Formal Case No. 1176*, Exhibit PEPCO (E)-5.

117 *Formal Case No. 1176*, Exhibit PEPCO (E)-5.

- Low Voltage ("GSLV") class by 1.2 percent, the Time Metered Medium General Service - Low Voltage (i.e., MGTLV) class by 11.2 percent, and its Time Metered General Service - Sub-Transmission (i.e., GT3B) class by 36.6 percent.[118]

Q. HAVE YOU COMPARED THE COMPANY'S RESIDENTIAL CUSTOMER CHARGES TO OTHER REGIONAL ELECTRIC UTILITIES?

A. Yes, and this analysis is presented in Exhibit OPC (A)-9. This analysis shows that the Company's current residential customer charge of $16.09 per month is noticeably greater than the regional average of $11.36 per month. This schedule surveys current residential and small commercial customer charges for major electric distribution companies operating in the Mid-Atlantic region. There are only five (out of 16) electric distribution utilities in the survey with residential customer charges greater than the Company's $16.09 per month. Further, Pepco's Maryland residential customer charges are 49 percent lower than the customer charges in the District.

Q. HAVE YOU COMPARED THE COMPANY'S COMMERCIAL CUSTOMER CHARGES TO OTHER REGIONAL ELECTRIC UTILITIES?

A. The Company's current small commercial customer charge of $32.88 per month is far greater than the average small commercial customer charge of $15.75 for other regional utilities. Furthermore, out of 16 electric distribution companies in the survey referenced earlier, none have a customer charge for small commercial customers that is greater than the Company's proposed $38.28 per month. Pepco's Maryland small commercial customer charges are 63 percent lower than the customer charges in the District.

---

[118] *Formal Case No. 1176*, Exhibit PEPCO (E)-5.

Q. DID YOU PREPARE AN ANALYSIS OF COSTS COMMONLY ASSOCIATED WITH CUSTOMER CHARGES?

A. Yes. That analysis is provided in Exhibit OPC (A)-10 and summarized in Figure 5 below. "Customer-related" expense accounts are those typically allocated on the basis of customers and can include: removing and setting meters; maintenance of meters; services expense; maintenance of service drops; meter reading expense; dispatch applications and orders; customer records and collections; customer billing and accounting; customer service and information; and sales expense. These costs can also include the depreciation expense associated with the service drop and meter plant accounts and property taxes, as well as the carrying charges (at the Company's requested rate of return) for the customer portion of services investment and 100 percent of the meters investment.

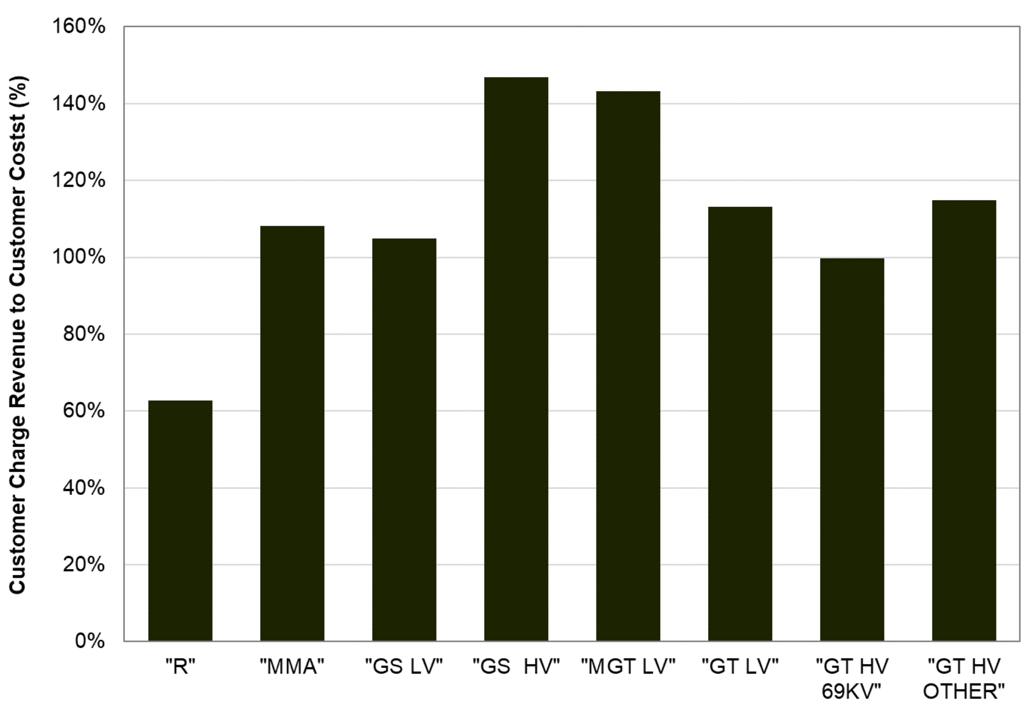

Figure 5: Summary of Customer Charge Revenues to Customer-Related Costs

Q. HOW DO THE COMPANY'S RESIDENTIAL CUSTOMER CHARGE REVENUES COMPARE WITH THE RESULTS OF ITS CCOSS?

A. As shown in Exhibit OPC (A)-10 the customer charge revenue associated with the R and MMA rate classes is 63 percent and 108 percent, respectively, of their class cost responsibility.

Q. HOW DO THE COMPANY'S GENERAL SERVICE CUSTOMER CHARGES COMPARE WITH THE RESULTS OF ITS CCOSS?

A. The results of the Company's non-residential classes' revenues are also shown in Exhibit OPC (A)-10. The Company's customer charge revenues for the GSLV and GSHV classes, respectively, are 105 percent and 147 percent of their class cost responsibility. The customer charge revenue for the Time Metered Secondary Service (MGT-LV) and Time Metered General Service low-voltage class (GTLV) are 143.3 and 113 percent of its cost-of-service responsibilities, respectively. The Time Metered high voltage classes, GTHV-69kv and GT-HV-Other, have customer charge revenues of 100 percent and 115 percent of their respective class cost responsibility.

Q. DO THESE RESULTS INDICATE ANY PRESSING NEED TO MAKE AN IMMEDIATE AND DRASTIC INCREASE IN CUSTOMER CHARGES, PARTICULARLY FOR THE RESIDENTIAL CLASS?

A. No. Most of the classes cover their customer-related costs through the current customer charge. Current residential customer charges do not fully cover current customer-related costs, but even for these customers the Company's current customer charge is estimated to cover 63 percent of their customer-related costs, or nearly two-thirds and more than a majority of such expenses. Likewise, the residential MMA class is estimated to currently recover 108 percent of its customer-related costs.

Q. WOULD THE PROPOSED INCREASES TO THE RESIDENTIAL CUSTOMER CHARGE BE AFFECTED BY ANY OTHER COMPANY RATE DESIGN PROPOSAL?

A. Yes. In addition to the proposed increases to the customer charge for the residential customer class, the Company additionally proposes to increase the discounted volumetric block rate of 1.055¢ for the first 400 kwh of use to 2.647¢ by RY3. This is an increase of 151 percent over a three-year period.

Q. SHOULD THE COMMISSION BE MINDFUL OF THE EFFECT OF THE COMPANY'S PROPOSED RATE DESIGN ON LOW-USE RESIDENTIAL CUSTOMERS?

A. Yes. There are numerous studies in the academic literature supporting the hypothesis that electricity is a "normal good."[119] That is, the consumption of electricity is directly correlated with household income level, meaning that higher-use electrical customers are typically higher income individuals and lower-use electrical customers are typically lower

[119] *See*, Exhibit OPC (A)-25, Alberini, A., W. Gans, D. Velez-Lopez. 2011, "Residential consumption of gas and electricity in the U.S.: The role of prices and income," Energy Economics 33, 870-881; Bernard, J., D. Bolduc, N. Yameogo, 2011, "A pseudo-panel data model of household electricity demand," Resource and Energy Economics 33(1), 315-325; Dax, P. 1987, "Estimation of Income Elasticity from Cross-Section Data," Applied Economics 19 (11), 1471-1482; Fell, H., S. Li, A. Paul. 2010, "A New Look at Residential Electricity Demand Using Household Expenditure Data," RFF DP 10-57; Fullerton, T. D. Juarez, A. Walke. 2012, "Residential Electricity Consumption in Seattle," Energy Economics; Reiss. P.C., and M. W. White, 2005, "Household electricity demand revisited," Review of Economic Studies 72, 853-858; and Swan L.G., V. I. Ugursan, 2009, "Modeling of end-use energy consumption in the residential sector: A review of modeling techniques," Renewable and Sustainable Energy Reviews 13, 1819-1835.

income individuals. These are important factual considerations the Commission should bear in mind.

Q. HAVE YOU CONDUCTED ANY ANALYSES EXAMINING THE RELATIONSHIP OF ELECTRICITY USAGE AND INCOME?

A. Yes, I am providing factual and analytical support for the Commission to consider. Page 1 of Exhibit OPC (A)-11 provides the results of an analysis I have performed using data from the 2020 Residential Electricity Consumption Survey ("RECS") produced by the United States Energy Information Administration ("EIA") and household data from the Census division in which the District is located.[120] The results show a positive relationship between electricity consumption (in kWh terms) and income. This clearly shows that as income increases, electricity consumption increases, and vice versa: as income decreases, electricity usage decreases.

Q. ARE THERE LOW-INCOME CUSTOMERS WHO WILL NOT BE AFFECTED BY THE COMPANY'S PROPOSED RATE CHANGES?

A. Yes. The Company states in its filing that its proposed rate increase for residential service customers will not affect customers receiving service under the RAD Program.[121] RAD provides a monthly credit (the RAC) that offsets the full customer and volumetric distribution charges of eligible residential customers who receive certification of income eligibility from the District's DOEE.[122]

---

[120] This census division also includes the states of Delaware, Florida, Georgia, Maryland, North Carolina, South Carolina, Virginia, and West Virginia. This is the most detailed level of aggregation available in the RECS.

[121] *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 32:6-9.

[122] *Id.* at 31:21-32:6.

Q. SHOULD THE COMMISSION IGNORE THE POTENTIAL EFFECT OF THE COMPANY'S PROPOSED RATE INCREASE ON LOW-INCOME RESIDENTIAL CUSTOMERS BECAUSE OF THE RAD PROGRAM?

A. No, this is an important factual and policy issue that the Commission should not ignore. As noted above, the RAD Program is income-restricted. Specifically, it is restricted to only those households that meet federal LIHEAP eligibility standards.[123] For the District, this amounts to $95,797 for a family of four and as little as $49,814 for a single occupant household.[124] Indeed, the Company reported an average of 37,850 customers in low-income programs the District in 2022,[125] with 25,814 of these customers specifically enrolled in RAD.[126] This means that nearly 13 percent of the Company's entire residential customer base is enrolled in some form of low-assistance program. There are many low-income persons living in the District that do not receive benefits through the RAD Program, and the Commission should not ignore this important fact.

Q. DO LOW INCOME HOUSEHOLDS SPEND PROPORTIONATELY MORE IN ELECTRICITY THAN HIGHER INCOME HOUSEHOLDS?

A. Yes. Lower income households spend a larger share of their income on electricity than higher income households. In other words, while households consume more electricity as

---

126 Exhibit OPC (A)-27, Response to OPC Discovery Request 3-45.

income increases, the share of their income they spend on electricity decreases as their income increases.

Q. WHAT DO THESE FINDINGS MEAN FOR LOWER-INCOME HOUSEHOLDS UNDER THE COMPANY'S RATE DESIGN PROPOSALS?

A. Lower-income households will likely be impacted negatively and in a fashion disproportionate to higher income households. As I noted earlier, electricity use increases as income increases, meaning that low-income households will likely use less, rather than more, electricity than their upper income counterparts. Therefore, the Company's proposal to increase volumetric rates will disproportionately impact those with lower usage and incomes in the District. Indeed, the Company's Conditional Demand Analysis ("CDA") based on its most recent appliance saturation study confirms my conclusions.[127]

Q. ARE THERE OTHER CONCERNS REGARDING THE PROPOSED INCREASES IN RESIDENTIAL CUSTOMER CHARGE?

A. Yes. The Company's proposal is inconsistent with the promotion of energy efficiency and conservation in the District for the simple reason that it places more costs into the fixed component of rates than in the variable component. This reduces economic incentives for ratepayers to control monthly utility bills through energy efficiency and conservation efforts, because only the variable component of bills is avoidable.

Q. HAVE OTHER COMMISSIONS RECOGNIZED THE DETRIMENTAL EFFECT INCREASED FIXED CHARGES HAVE ON ENERGY EFFICIENCY?

---

[127] *Formal Case No. 1176*, PEPCO (E)-16.

A. Yes. In rejecting a request by Northern States Power Company to increase customer charges[128] as part of a larger rate design proposal, the Minnesota Public Utilities Commission recognized the need to allow customers the opportunity to control their monthly bills by reducing energy usage.

> Monthly customer charges are an important component of the Company's Residential and Small General Service rates by facilitating recovery of the costs caused by each customer that do not vary with the amount of energy used. However, higher fixed customer charges discourage customers from conserving energy and investing in renewable energy by reducing the impact of these efforts on the customers' bills. Customer charges also tend to confuse and alienate customers by impairing customer understanding of their energy bills. The Commission notes that Minn. Stat. §216B.03 requires the Commission to design rates to encourage energy conservation and renewable-energy use to "the maximum reasonable extent." Considering this statutory mandate and the evidence submitted by the parties, the Commission agrees with the ALJ that it is reasonable and appropriate to lower the monthly customer charge for the Residential and Small General Service classes to $ 6.00.[129]

Q. IS THE MINNESOTA COMMISSION ALONE IN ITS BELIEF THAT HIGH FIXED CHARGES DISCOURAGE EFFICIENT USE OF ENERGY?

A. No. A research document presented for consideration by the membership of the National Association of Regulatory Utility Commissioners ("NARUC") lists Straight-Fixed Variable ("SFV") rate design as an alternative to delink utility revenue from sales. A SFV places all fixed-related costs to fixed charges while relegating only variable charges to

---

128 *In the Matter of the Application of Northern States Power Company, dba Xcel Energy, for Authority to Increase Rates for Electric Service in the State of Minnesota*, Minnesota Public Utilities Commission, Docket No. E-002/GR-21-630, Findings of Fact, Conclusions, and Order, at 114 (July 17, 2023).

129 *Id.*at 116-117.

volumetric rates. The NARUC research noted this type of rate design was problematic because of its effects on customer incentives to conserve energy:

> **Straight-Fixed Variable Rate Design.** This mechanism eliminates all variable distribution charges and costs are recovered through a fixed delivery services charge or an increase in the fixed customer charge alone. With this approach, it is assumed that a utility's revenues would be unaffected by changes in sales levels if all its overhead or fixed costs are recovered in the fixed portion of customers' bills. <u>This approach has been criticized for having the unintended effect of reducing customers' incentive to use less electricity or gas by eliminating their volumetric charges and billing a fixed monthly rate, regardless of how much customers consume</u>.[130]

Q. HAS ANY NATIONAL PUBLIC POLICY ANALYSIS NOTED THE EFFICIENCY DISINCENTIVES ASSOCIATED WITH SFV-TYPE RATE DESIGNS?

A. Yes. The National Action Plan for Energy Efficiency ("NAPEE"), a joint venture of the U.S. Department of Energy and U.S. Environmental Protection Agency, published a whitepaper on various rate design effects on encouraging energy efficient behaviors. The NAPEE postulated that SFV had a detrimental effect on economic signals to encourage customers to change energy usage behavior and investments in energy efficiency devices, and specifically noted that such disincentives persist even when applied to individual components of a customer's utility bill, such as SFV for strictly distribution services:

> Because [SFV] tends to shift costs out of volumetric charges, it tends to reduce customers' efficiency incentive, because the marginal price of additional consumption is reduced. <u>While SFV rates are being considered to better reflect the utility's costs behind the rate, these rates do not encourage customers to change energy usage behavior or invest in</u>

[130] "Decoupling for Electric & Gas Utilities: Frequently Asked Questions (FAQ)" (September 2007), Grants & Research Department, National Association of Regulatory Utility Commissioners, p. 5. (Emphasis added).

> efficiency technologies. Such customer disincentives persist even when SFV rates are applied to individual components of the bill, such as charges for distribution service.[131]

Q. WHAT ARE YOUR CUSTOMER CHARGE RECOMMENDATIONS AND CONCLUSIONS?

A. Given the important factual and policy considerations involved, I recommend that the Commission direct the Company to maintain customer charges at their current levels.

Q. PLEASE EXPLAIN WHY YOU RECOMMEND THAT THE COMMISSION DIRECT THE COMPANY TO MAINTAIN CUSTOMER CHARGES AT THEIR CURRENT LEVELS.

A. I make this recommendation in part because the Company's customer charges are already on the high side of other regional utilities and do not need to be increased any further. Additionally, residential customers have seen significant cumulative increases in customer charges over the past few rate cases. Since Formal Case No. 1053 in 2006, residential customers have seen fixed customer charges increases of a whopping 705 percent, from $2.00 per month to $16.09 per month. These significant and ongoing increases have left the District's residential customer charges at a level noticeably higher than the equivalent charges for residential customers living in the Company's Maryland service territory. Furthermore, District ratepayers will not be able to mitigate these increases in fixed

[131] National Action Plan for Energy Efficiency, "Customer Incentives for Energy Efficiency Through Electric and Natural Gas Rate Design" at 13-14, prepared by William Prindle, ICF International, Inc. (September 2009) (emphasis added), available at https://www.epa.gov/sites/production/files/2015-08/documents/rate_design.pdf.

customer charges through participation in District energy efficiency programs or other conservation efforts.

VII. PEPCO'S MYP REQUEST

A. Overview of MYP

Q. PLEASE DESCRIBE THE MYP.

A. The MYP was originally proposed in Formal Case No. 1156 under the premise that it would assist the Company in making significant long-term investments to meet the District's policy goals and changing needs of its customers,[132] with a particular emphasis on investments in grid modernization and infrastructure required to facilitate District goals of climate action, transportation electrification, and increased resilience.[133] The MYP was originally proposed as a three-year mechanism (2020-2022) and included a set of proposed PIMs to incentivize performance and compliance with policy objectives.[134] The original proposal was ultimately "enhanced" in the last base rate case ("enhanced MYP") in order to reduce proposed near-term rate increases and to provide an increased set of residential and commercial customer assistance programs.[135]

Q. DID THE COMMISSION APPROVE THE COMPANY'S PROPOSED MYP IN FORMAL CASE NO. 1156?

---

[132] Exhibit OPC (A)-28, *Formal Case No. 1156,* Exhibit PEPCO (A), Direct Testimony of David M. Velazquez at 8:4-5.

[133] *Id.* at 8:21 to 9:2.

[134] *Id.* at 8:13-17.

[135] Exhibit OPC (A)-29, *Formal Case No. 1156,* Exhibit PEPCO (5B) (McGowan) at 15:19-22.

A. No. The Commission rejected both Pepco's original MYP and its enhanced MYP as proposed.[136] Instead, the Commission approved a modified enhanced MYP with a reduced revenue requirement recognizing the regulatory mechanism's reduced financial risk.[137] The Commission's modified enhanced MYP also required additional Pepco shareholder-funded customer benefit programs for residential, small commercial, and streetlight customers in the District,[138] and a revised set of tracking PIMs focused on the District's climate and clean energy goals.[139]

Q. WAS THE MODIFIED ENHANCED MYP APPROVED AS A PERMANENT CHANGE IN REGULATORY METHODS IN THE DISTRICT?

A. No. The Commission was clear in Formal Case No. 1156 that the modified enhanced MYP was approved as a pilot program and that there would be an explicit process by which overall performance and effectiveness of the MYP would be evaluated.[140]

> With respect to customer benefits, the Modified [Enhanced MYP] is designed to among other things, make rates more predictable for customers, with rate increases spread gradually over multiple years. In this case, the prolonged proceeding and the exigency of the COVID pandemic led the Commission to <u>approve a pilot 18-month [Enhanced MYP]</u> with offsets through 2022 that lessons the impact of Pepco's [Enhanced MYP] rate increase. <u>Adopting the Modified [Enhanced MYP] as a pilot program provides the Commission, the Parties, and other stakeholders with an opportunity to improve the [MYP] process and prudently</u>

137 *Id.*

138 *Id.*

139 *Id.*

140 *Id.*, ¶ 474.

> evaluate the overall performance and effectiveness of the Modified [Enhanced MYP].[141]

The Commission also explained that it "will determine on a case-by-case basis whether the principles of the framework have been met in the proposed AFOR under the specific facts and circumstances of the case."[142]

Q. DID THE COMMISSION PROVIDE ANY GUIDANCE ON CONSIDERATION OF MYP OR SIMILAR MECHANISMS IN FORMAL CASE NO. 1156?

A. Yes. The Commission's decision was based upon broad considerations regarding "paradigm shifts" away from traditional ratemaking toward AFORs.[143] The Commission concluded that review of any AFOR, not just an MYP, must be deliberative in nature due to the potential scope of changes, and recognized that such changes may require multiple rate proceedings to fully implement.[144]

> While the statute permits the Commission to adopt AFORs, the Commission's review of any changes to the traditional ratemaking methodology must be deliberative, paying careful attention to the structure and framework for the evaluation of AFORs so that unintended operational or financial outcomes are mitigated and managed. The District's electric and natural gas utilities combined, as of their last fully litigated rate case, collect from ratepayers $691.45 million per year to support the safe and reliable operations of energy distribution systems valued at $1.9 billion. In considering and implementing changes as to how the costs of these systems are accounted for and recovered from ratepayers, the Commission must carefully consider how its actions impact the operational incentives of the utilities, ensure that it maintains the financial stability and

142 *Formal Case No. 1156,* Order No. 20737, ¶ 96.

143 *Formal Case No. 1156*, Order No. 20755, ¶ 473.

144 *Formal Case No. 1156*, Order No. 20273, ¶ 86.

> flexibility of the utilities, and promote the utilities' continued safe and reliable operations over time. The Commission recognizes that there will not be quick or rapid changes in rate review and recovery given the importance of utility operations to the District and the scope of their operations. We believe that any changes to the traditional ratemaking methodology may require multiple rate proceedings to fully implement AFORs.[145]

Q. WHAT SPECIFIC GUIDANCE DID THE COMMISSION PROVIDE REGARDING AFORS IN FC 1156?

A. The Commission established an overarching framework as a starting point for which AFOR proposals would be reviewed including the consideration of PIMs, that advance or otherwise align with District public policy goals,[146] and indeed the Commission held that "any [MYP] that is adopted should be accompanied by PIMs."[147]

Q. WERE PIMS PART OF THE ORIGINAL PILOT PROGRAM APPROVAL?

A. No, since the Commission rejected the Company's originally proposed PIMs which mainly focused on promoting service reliability. The Commission found such a limited set of PIMs unnecessary since it already has Electric Quality of Service Standards ("EQSS") governing reliability performance.[148] Instead, the Commission approved a set of initial tracking (or "reporting-only") PIMs that, once properly designed, could be turned into fully functioning PIMs with financial penalties associated with poor performance.[149] The Commission ordered Pepco to reconvene an existing PIMs Working Group to collaborate

---

[145] *Formal Case No. 1156*, Order No. 20273, ¶ 86, emphasis added.

[149] *Id.*, ¶ 169.

with interested parties on appropriate data measurement methodologies for the approved tracking PIMs, and implied that it envisioned this collaborative process being an ongoing process to develop additional financial/tracking PIMs as needed in the future.[150]

Q. HAS THE COMMISSION OR THE PIMS WORKING GROUP DEVELOPED FULLY FUNCTION PIMS FOR USE WITH THE COMPANY'S MYP?

A. No, there are no approved PIMS in place at the current time. To date, the PIMs Working Group has not only been unable to develop a comprehensive set of working PIMs, it has still yet to finalize appropriate data measurement methodology associated with the Commission-implemented tracking PIMs from the last base rate case.

Q. WAS A REVIEW PROCESS ENVISIONED FOR THE MODIFIED ENHANCED MYP?

A. Yes. The current procedural schedule clearly states that the existing MYP was approved as a pilot mechanism and that further review of the lessons learned and experiences with the program would be important in considering any proposed new MYP mechanism.[151]

B. Evaluation of Existing Pepco's MYP Mechanism

Q. WHAT POTENTIAL MYP BENEFITS WERE IDENTIFIED IN FC 1156?

A. Ten quantitative and qualitative benefits were purported to arise from adoption of the MYP including: (1) facilitating investments that support the District's energy policy goals; (2) providing customers, the Commission, and interested parties a longer-term view of future capital investments and O&M plans before the utility makes those investments; (3)

---

[150] *Id.*, ¶ 173.

[151] *Id.*

providing customers with rate predictability over the MYP's term; (4) providing a decrease in the administrative burden and cost for the Commission and stakeholders by reducing the frequency of annual rate case filings; (5) protecting customers and provide incentives to the Company to reduce costs and improve operational efficiency through the proposed Annual Reconciliation Filing; (6) aligning customer rates and reflect the current cost of providing service to customers; (7) increase the level of transparency and reporting to customers, the Commission, and stakeholders; (8) enhancing Commission oversight through advance review of the Company's total capital investment plan and proposed performance levels, with annual reporting and reviews of certain variances to those approved plans over the term of the MYP and again at its conclusion; (9) providing for significant automatic financial penalties if the Company did not meet Commission-approved performance criteria; and (10) enhancing certainty of spending for the MYP's term, leading to improved investment planning that would create jobs and promote economic development.[152]

Q. HAS THE COMPANY "PROVED UP" ANY OF THESE ASSERTED BENEFITS IN ITS CURRENT FILING?

A. No, Pepco has not provided evidence or analysis to support a finding of fact that its proposal will provide these benefits. Rather, the Company provides open-ended assertions regarding MYP performance including statements like "the MYP has allowed for more

152 *Formal Case No. 1176*, Exhibit PEPCO (2A), Direct Testimony of Elizabeth M. D. O'Donnell at 3:1 to 4:4; *citing*, *Formal Case No. 1156*, Exhibit PEPCO (3B), McGowan Additional Supplemental Direct Testimony at 9-21, submitted January 21, 2020, and *Formal Case No. 1156*, Exhibit PEPCO (4B), McGowan Rebuttal Testimony at 9-17, submitted April 8, 2020.

timely recovery of investments over the MYP," that the MYP has allowed the Company to "invest at the pace required to meet the District of Columbia's and the Commission's decarbonization and clean energy goals."[153] The Company also states that the MYP provided a longer-term, forward-looking view of proposed business and capital investment plans[154] and rate predictability for customers during its term.[155] Importantly, however, the Company did not provide any quantifiable and measurable review of supposed historic benefits of the MYP, even while claiming that the MYP's reduction in administrative burden and costs associated with annual rate case filings was "quantitative and measurable."[156] The one exception to this, was a report, prepared by NERA, that purports to show the economic benefits of the MYP on the District's economy.

Q. PLEASE EXPLAIN THIS NERA REPORT OF PURPORTED MYP BENEFITS.

A. The Company provided an economic benefits study conducted by NERA Economic Consulting (hereafter "NERA Report") estimating the economic impact of the Company's actual investments in 2022 and proposed capital investments from 2023 through 2026.[157] This analysis supposedly found that Pepco's plan is estimated to support over 3,800 full-time equivalent jobs, contribute more than $580 million in value added to gross domestic product and $26 million in tax revenue in the District.[158]

158 *Id.*

Q. HOW CAN LARGE CAPITAL INVESTMENTS IMPACT A LOCAL ECONOMY?

A. Capital investment programs like those purportedly "facilitated" by the MYP can lead to both positive and negative economic impacts. For instance, capital investments can lead to a number of construction, engineering, and other employment opportunities in the local economy. These capital expenditures can lead to ripple "multiplier" effects since every dollar spent in the local economy is supported by a variety of other activities and investments.

Q. DO PROGRAMS SUCH AS THE MYP COME WITH ANY COSTS?

A. Yes, this is an important factual issue that the NERA Report fails to consider. Capital investment programs, like those purportedly facilitated by the MYP, need to be financed, and that financial support, in the case of regulated utility investment, comes from the rates paid by retail ratepayers. These rate increases, however, represent a cost since they reduce household disposable income and increase costs to businesses and industries. Reductions in household income and increases in business costs, in turn, reduce the amount of money spent on goods and services, which in turn, leads to negative ripple or multiplier effects in a regional economy, in same way program-related expenditures result in positive ripple effects. A complete review of the MYP, therefore, needs to consider the "net benefits" of overall program costs and benefits. While the NERA Report considered the local "benefits" of these purportedly MYP-facilitated capital investments, the study does not offset such benefits with the costs of the investment program, namely, the rate impacts.

Q. HAVE YOU ESTIMATED THE NET BENEFITS OF THE COMPANY'S PURPORTED MYP INVESTMENT PROGRAM?

A. Yes, and this is presented in Confidential Exhibit OPC (A)-12 and pages 18-23 show that the Company's MRP Pilot has led to, and will continue to lead to, negative net economic benefits. My findings are that the MRP Pilot in conjunction with the MYP proposal will have the following economic effects:

- A contraction of economic output of over $2.7 billion on a net-present value ("NPV") basis.
- An employment reduction of 41,000 job-years;
- A $1 billion reduction in overall wages; and
- A $1.2 billion reduction in local GDP.

C. Evaluation of Alternative Regulation in General

Q. HAS THE COMPANY COMPARED ITS PERFORMANCE TO OTHER AFORS?

A. No. The Company has conducted no specific analysis looking at any of the ten different benefits that purportedly have arisen from the MYP nor have they compared/contrasted their AFOR performance with best practices in other regulatory jurisdictions. My experience, however, is that, to date, few AFORs have led to results that provide clear and unequivocal ratepayer benefits.

Q. HAVE YOU EXAMINED AFOR PERFORMANCE IN OTHER JURISDICTIONS?

A. Yes, and that analysis is provided in Exhibit OPC (A)-13. For purposes of this analysis, AFORs are limited to the major "paradigm shifting" forms of regulation that include formula rate plans ("FRPs"), performance-based ratemaking ("PBR") and MYP mechanisms. My analysis finds that, to date, no major form of AFOR has led to meaningful or measurable ratepayer benefits, including no sustainable or distinctly measurable improvement in reliability or quality of service.

Q. WHAT CONCLUSIONS DO YOU REACH FROM THIS ANALYSIS?

A. As shown in Exhibit OPC (A)-13, no major form of AFOR has led to any meaningful or measurable ratepayer benefits in other jurisdictions. Indeed, no one single state adopting an AFOR has shown outcomes that can be held out as an unequivocal "success" for ratepayers. Specifically, AFORs have generally led to:

- Deterioration in utility capital investment discipline with significant increases in rate base;
- Large rate increases with very few rate decreases or earning sharing opportunities;
- No measurable or sustainable improvement in utility operating cost efficiencies; and
- No sustainable or distinctly measurable improvement in reliability or quality of service.

D. Review of the Company's MRP Pilot

Q. DID YOU REVIEW SUPPLEMENTAL TESTIMONY IN THIS CASE RELATED TO THE MRP PILOT?

A. Yes, I reviewed the Supplemental Testimony submitted by Pepco on August 31, 2023, which the Company was required to submit per Order 21886. This supplemental filing reviewed the MRP Pilot, including lessons learned by the Company, as well as an explanation, in quantitative and qualitative terms, as to the benefits of the MRP Pilot.

Q. BASED ON YOUR REVIEW OF PEPCO'S TESTIMONY AND FILING REGARDING THE MRP PILOT SHOULD THE COMMISSION ADOPT A MULTIYEAR PLAN?

A. No. Pepco's pre-filed testimony and exhibits contain no analysis or support for findings that (a) the MRP pilot, to date, has provided any ratepayer benefits and (b) that moving to the proposed MYP will result in any *bona fide* and measurable public benefits. To date, the Commission has no PIMs to govern a future MYP and will likely not have any by the conclusion of this proceeding. Failure to adopt PIMs or any other form of performance accountability in this proceeding is inequitable since it provides clear and unequivocal benefits to the Company and its shareholders but no measurable benefits to the District's ratepayers. It is virtually impossible to establish a set of rates that are fair, just, and reasonable under such conditions and under a framework like that proposed by the Company. Therefore, the Commission must also reject the proposed MYP at the current time.

Q. WHAT KIND OF BENEFITS SHOULD RATEPAYERS EXPECT TO SEE FROM A MULTIYEAR PLAN?

A. Ultimately, the set of performance metrics for a multiyear plan, such as the MRP Pilot and the proposed MYP, should be straightforward, measurable, and transparent and should focus on big-pictures goals: lower and/or more affordable rates; greater operating and cost efficiencies; and lower GHG emissions, particularly Pepco's own Scope 1 GHG emissions.

Q. WILL ENERGY AFFORDABILITY IMPROVE IF THE COMPANY'S MRP PILOT IS CONTINUED ON A PERMANENT BASIS?

A. No, and I discussed this outcome in my discussion of affordability earlier in my testimony. Figure 6 below comes from the affordability analysis I conducted for the District (OPC Exhibit (A)-2) and shows that some of the District's most vulnerable ratepayers will be adversely impacted if the MYP is approved.

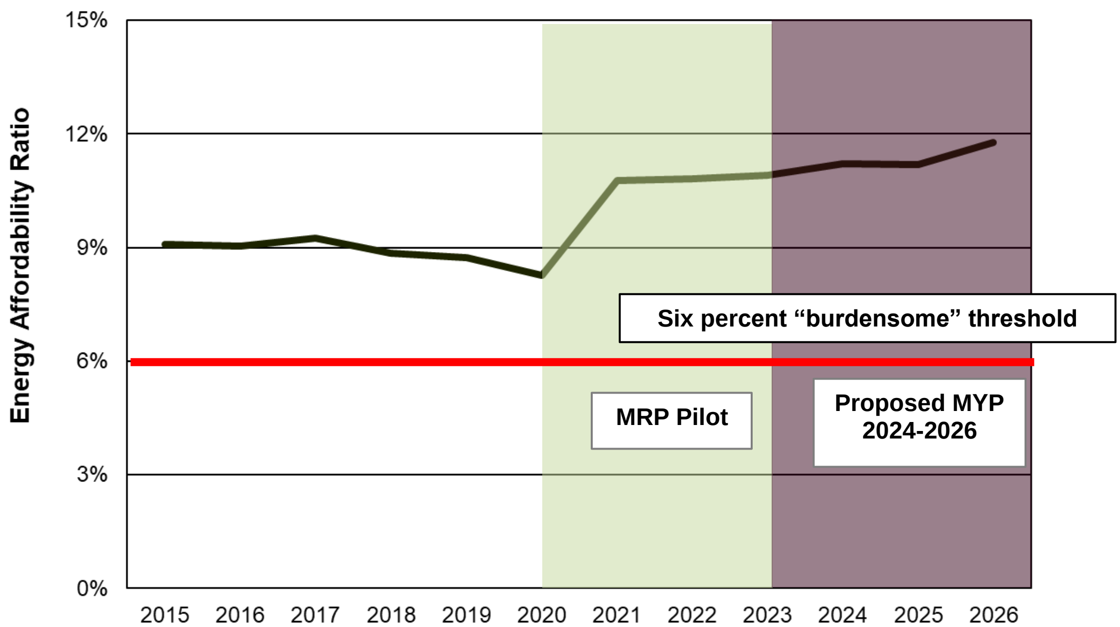

Figure 6: Energy Affordability Ratio for Customers at or below 15th income percentile

Q. DID PEPCO'S RATE COMPETITIVENESS IMPROVE DURING THE MRP PILOT?

A. No. Exhibit OPC (A)-13 includes a section examining a number of different metrics (prices, costs, capital investments) before and during the MRP Pilot. These metrics have been compiled for both the Company and other regional peer investor-owned utilities ("IOUs"). Pages 63 to 69 provide a comparison of the Company's residential and commercial retail rates (average non-fuel revenues) relative to peer utilities. The table and charts on these pages show that Pepco's retail rates have not improved during the MRP Pilot period. Specifically, Pepco has consistently had the 9th highest residential rates in the region (out of a peer group of 14 utilities) since 2017. Pepco's commercial rates have grown during the MRP Pilot period such that the Company has the 12th highest rates in the region.

Q. DID PEPCO SEE ANY IMPROVEMENTS IN ITS OPERATING COST EFFICIENCIES DURING THE MRP PILOT?

A. No. Pages 70 to 76 of Exhibit OPC (A)-13 show a variety of comparisons of both the Company's O&M and A&G costs. Over the past year of available information, Pepco has not seen demonstrative improvement in its O&M costs relative to peer utilities and, in fact, has seen its ranking deteriorate recently. While the Company's A&G performance has improved, that improvement seems highly correlated with its prior merger and, if anything, recent trends suggest a halt in those A&G cost improvements over the past year of available information.

Q. DID PEPCO SEE ANY IMPROVEMENTS IN ITS CAPITAL COST EFFICIENCIES OVER THE MRP PILOT PERIOD?

A. No. As shown in pages 77 to 81 of Exhibit OPC(A)-13, Company growth in net distribution plant in service has constantly outpaced regional peer utilities since 2013. In recent years Company net distribution plant per MWh of load has grown to the highest of all regional peer utilities, without any sign of moderation from the MRP Pilot.

Q. IS THERE ANY EVIDENCE TO SUGGEST THAT GHG EMISSIONS IN THE DISTRICT IMPROVED DUE TO THE MRP PILOT?

A. No. Page 83 of Exhibit OPC (A)-13 show that GHG emissions in the District have been steadily declining through the entirety of the period 2010 through 2020. Page 84 of Exhibit OPC (A)-13 furthermore shows that non-residential GHG emissions in the district fell from approximately 4.2 million metric tons of CO_2 equivalents ("MMTCO2e") in 2010 to approximately 2.1 MMTCO2e in 2020, a 50 percent decline over the course of the decade without any utility intervention. So, while it is possible that the District saw reduced GHG emissions during the course of the MRP Pilot, there is little evidence to suggest these reductions were due to the MRP Pilot.

E. The MYP in Relation to Climate and Clean Energy Goals

Q. ARE THERE ANY OTHER REASONS TO REJECT THE COMPANY'S REQUESTED MYP?

A. Yes. The capital investments identified to be recovered through the MYP are not designed to meet the District's climate and clean energy goals, but, instead, appear to be designed to meet its normal public service obligations. OPC's engineering expert, Mr. Kevin Mara, notes that several of the Company's proposed MYP capital investment programs are comparable to those he has seen repeatedly over the past several years, up to, and including those in which the Company was regulated using "traditional" cost of service methods. Mr. Mara shows in his direct testimony that over 90 percent of the Company's proposed MYP investments are dedicated to the replacement of aged infrastructure and other "business as usual" investments, not those dedicated to clean energy or reducing GHG emissions. There is no showing that these business-as-usual and "like for like" investments cannot be facilitated thought traditional regulation, much like they were prior to the MRP Pilot.

Q. IS PEPCO ABLE TO MATCH ITS PROPOSED MYP INVESTMENTS TO SPECIFIC CLEAN ENERGY OR CLIMATE GOALS?

A. No. Pepco has not been able to identify which of its MYP capital investments are specifically designed to meet the District's climate and clean energy goals[159] nor, more importantly, has the Company been able to identify how it will measure the success of such investments in meeting these climate and clean energy goals.[160]

Q. HAS THE COMMISSION RECENTLY EXPRESSED ANY RESERVATIONS ABOUT THE APPROVAL OF ILL-DEFINED CLIMATE-RELATED INVESTMENTS?

A. Yes. The Commission recently considered, and ultimately rejected, Washington Gas Light Company's ("WGL's") proposal to fund six future climate initiatives through a new Climate Action Recovery Tariff ("CART").[161] The Commission based its rejection of the CART proposal on the premature nature of WGL's request, observing:

> Until projects have been approved by the Commission, whether in *Formal Case No. 1167* or other proceedings, according to the mechanism approved in *GD2019-04-M*, there should be no cost recovery for these unapproved programs at this time.[162]

Q. COULD CERTAIN INVESTMENTS PROPOSED BY THE COMPANY BE USEFUL FOR GRID MODERNIZATION AND IMPROVING THE DISTRICT'S CLEAN ENERGY CAPABILITIES?

---

[159] Exhibit OPC (A)-30, Pepco's Response to OPC Data Request 4-1(b).

[160] Exhibit OPC (A)-30, Pepco's Response to OPC Data Request 4-1(a).

[161] *Formal Case No. 1169, In the Matter of the Application of Washington Gas Light Company for Authority to Increase Existing Rates and Charges for Natural Gas Service,* ("Formal Case No. 1168"), Order No. 21939 at ¶ 430, rel. December 22, 2023 ("Order No. 21939").

[162] Order No. 21939, ¶ 430.

A. Mr. Mara notes that the Advanced Distribution Management System ("ADMS") has the ability to make important contributions to grid modernization but, to date, there is not clear linking of specific and quantifiable annual benefits and costs needed to attain those benefits. Furthermore, the Company has not clearly shown how its clean energy and climate investments cannot be facilitated under traditional forms of regulation.

Q. WHAT CONCERNS DO YOU HAVE WITH PEPCO'S ADMS PROPOSAL WITHIN THE CONTEXT OF A REGULATORY FRAMEWORK?

A. If anything, the Company's inability to show any unique need nor performance standard for its clean energy investments, including the ADMS, begs for a tighter form of traditional regulation, not a MYP. The Company's ADMS alone serves as a good reason why the Commission should utilize traditional regulation and not an MYP:

- The ADMS is small relative to the Company's proposed MYP capital investments.
- The Company cannot specifically identify and quantify the ADMS benefits, many of which may not start to materialize until as late as 2029.
- There is no well-defined process by which these investments will be rolled out, their composition, and the input that stakeholders, including the Commission, will have in this process.

Q. HOW LARGE ARE THE ADMS INVESTMENTS RELATIVE TO THE COMPANY'S TOTAL PROPOSED MYP CAPITAL SPENDING AMOUNTS?

A. Table 1 below compares the Company's annual ADMS investment levels relative to its total proposed MYP capital budget. The ADMS is relatively small, less than one percent of total capital spending, on average, over the MYP period. There is nothing in the ADMS investment levels that are large or volatile enough to justify some form of alternative regulation nor some alternative to a MYP such as a special, limited one-time capital tracker to address the goals of this program alone.

Table 1: Comparison of Annual ADMS to Total MYP Capital Budget

	2024	2025	2026	Total MYP
	($000)			
Advanced Distribution Management System (ADMS)				
Project 268: ADMS Implementation	$ 3,845	$ 3,460	$ 1,640	$ 8,945
Project 294: ADMS Covergence-Stage 2	-	-	3,485	3,485
Total ADMS	**$ 3,845**	**$ 3,460**	**$ 5,126**	**$ 12,430**
Total Executive Capital Budgeted Through MYP Period	**$ 456,190**	**$ 476,906**	**$ 489,551**	**$ 1,422,647**
Percent ADMS of Total Capital Budgeted	**0.84%**	**0.73%**	**1.05%**	**0.87%**

Q. HAVE THE DETAILS AND FUNCTIONALITIES OF THIS PROPOSED INVESTMENT BEEN CLEARLY DEFINED?

A. No. Mr. Mara notes that many of the ADMS functionalities could help to facilitate distributed energy resource ("DER") development in the District. For instance, the Enterprise Asset Management Program is expected to be a precursor for the Company's Distributed Energy Management System ("DERMS") and purportedly will allow for the interconnection and control of various different technologies and resource ownership models. However, DERMS itself is part of a future phase of the ADMS implementation that is not projected for deployment until 2029. Thus, the details and functionalities of this program are yet to be fully scoped or defined.[163] Furthermore, Mr. Mara notes that the

[163] Exhibit OPC (A)-31, Pepco's Response to OPC Data Request 6-20.

ratepayer benefits of this program, from an engineering perspective, cannot be assessed at the current time.

Q. DOES A MYP FACILITATE STAKEHOLDER PARTICIPATION AND ACCOUNTABILITY?

A. No. The MYP does not include nor assure a proper framework for the Commission, OPC, and other stakeholders to assure that investments made by the Company are prudent, will not lead to technologies and processes that will be quickly obsolete and stranded, nor will a MYP facilitate the kind of interconnection and diversity of ownership envisioned in grids of the future. This later consideration is important, particularly as it relates to investments facilitating the future deployment of the DERMS. The DERMS is purportedly designed to facilitate various different technologies and ownership types, so it is incumbent that stakeholder input, of all types, be facilitated. Such input requires more regulation, not less regulation typical of a MYP and other AFORs. .

Q. WHAT IS THE BEST FORM OF REGULATION TO ADDRESS THE DISTRICT'S CLIMATE CHANGE GOALS?

A. The goals of today's clean energy agenda require greater regulatory oversight and input to assure that a wide range of resource options, participants, and potential outcomes are considered. The goals of most clean energy agendas are societal in nature, and have been, and should continue to be determined by public policy, not by regulated utilities and their shareholders. AFORs effectively decouple prices from costs and allow utilities (and by default, their shareholders) to establish priorities that maximize profits, not necessarily a clean energy/climate agenda. AFORS allow prices to change, with little to no ongoing regulatory oversight and input. Once the "cast-off" rates are set, regulators are put in a passive position to hope that positive regulatory outcomes, assuring ratepayer benefits, are attained. This is particularly problematic if no *ex-ante* performance standards or benchmarks (with penalties for negative outcomes) are established.

Q. DOES A "HANDS-OFF" FORM OF REGULATION WORK WELL AT ASSURING PERFORMANCE GOALS ARE MET?

A. No. This is not the 1980s, and in the absence of very clearly defined standards, with penalties and other forms of accountability, regulators need to be more actively engaged to assure that ratepayers are protected and that other clean energy goals, including GHG emission reductions, are met. To date, the Commission itself has had a difficult time defining what performance standards it wants from Pepco placing all performance risk of the MRP Pilot exclusively upon ratepayers. If the Commission does that once again, by approving the Company's proposed MYP, without a clearly defined, fully vetted set of performance standards agreed upon by a diverse group of impacted stakeholders, it will be difficult to assure that rates are fair, just, and reasonable.

Q. WHAT REGULATORY APPROACH DO YOU RECOMMEND THE COMMISSION ADOPT IN ORDER TO HELP ACHIEVE THE DISTRICT'S CLIMATE

A. To assure both forward movement on the District's clean energy agenda, and the protection of ratepayers, a return to traditional regulation is the best option. Pepco's pre-filed testimony and exhibits contain nothing that would suggest, much less demonstrate, that moving back to traditional regulation will be harmful to that clean energy agenda. A return to traditional oversight methods will ensure that rates are set in a fashion consistent with their public policy requirements.

VIII. BILL STABILIZATION ADJUSTMENT

A. BSA Background

Q. PLEASE DESCRIBE THE BSA.

A. The BSA is a rider adjustment that is designed to recover differences between authorized test year RPC and actual base RPC collected by the Company. In proposing the BSA in 2009, the Company claimed that the mechanism would "decouple revenues from variation in kWh sales per customer."[164] The BSA is designed to provide the Company with stable revenue streams based on test year revenue requirements,[165] by insulating the Company from changes in sales resulting from weather, price elasticity, building standards, expanded energy efficiency programs, and changes in appliance efficiency.[166] The BSA, it was argued, would increase the stability of customer bills and reduce the Company's financial risk, eliminate the disincentive for the Company to promote energy efficiency, and help ensure fixed-cost recovery.[167]

Q. HOW IS THE BSA CALCULATED?

A. The BSA is computed by comparing the normalized per-customer monthly test year revenues from the Company's base rate case proceeding for each customer class, with the actual per-customer revenues, adjusted for any major service outages. This difference,

---

164 *See Formal Case No. 1053*, Order No. 14712, ¶ 340.

165 *Id.*

166 *Id.*, ¶ 341.

167 *Id.*, ¶ 343.

along with any over or under-collections from previous months, is divided by forecasted kWh sales to derive a volumetric adjustment for the BSA.

Q. HOW DOES THE BSA COMPARE TO OTHER DECOUPLING MECHANISMS USED BY SOME UTILITIES ACROSS THE COUNTRY?

A. The BSA is an RPC-based form of revenue decoupling that allows the Company to adjust revenues between rate cases. An RPC-based revenue decoupling mechanism uses a commission-authorized revenue requirement as the numerator, and test year customers, as the denominator. Weather-normalized actual RPC collected by the utilities are then compared against this authorized RPC benchmark, with revenue surpluses credited to customers and revenue deficiencies assessed as a surcharge on customer bills. With respect to Pepco, this comparison is done on a monthly basis, though other utilities have revenue decoupling mechanisms that are reconciled on a quarterly or annual period.

Q. HAVE YOU REVIEWED THE HISTORIC PERFORMANCE OF THE COMPANY'S BSA?

A. Yes. Exhibit OPC (A)-14 presents historical BSA credits and debits from December 2009, when the adjustment first went into effect, to July 2023. This analysis shows that in general, revenues recovered through the BSA have grown significantly since it was first implemented in late 2009. The BSA recovered less than $3.2 million in 2010 then grew substantially, recovering almost $16.2 million in 2015. While the $16.2 million figure from 2015 was down from the total BSA adjustment for 2014 of nearly $22.0 million, revenues recovered through the BSA continued to grow after 2015. In 2018 the BSA recovered more than $26.2 million, and by 2022, the mechanism recovered nearly $36.1

million. In just the first eleven months of 2023 the BSA has totaled nearly $40.1 million in recoveries. Over the entire history of the BSA, the Company has recovered an astounding **<u>$294.0 million</u>** from ratepayers.

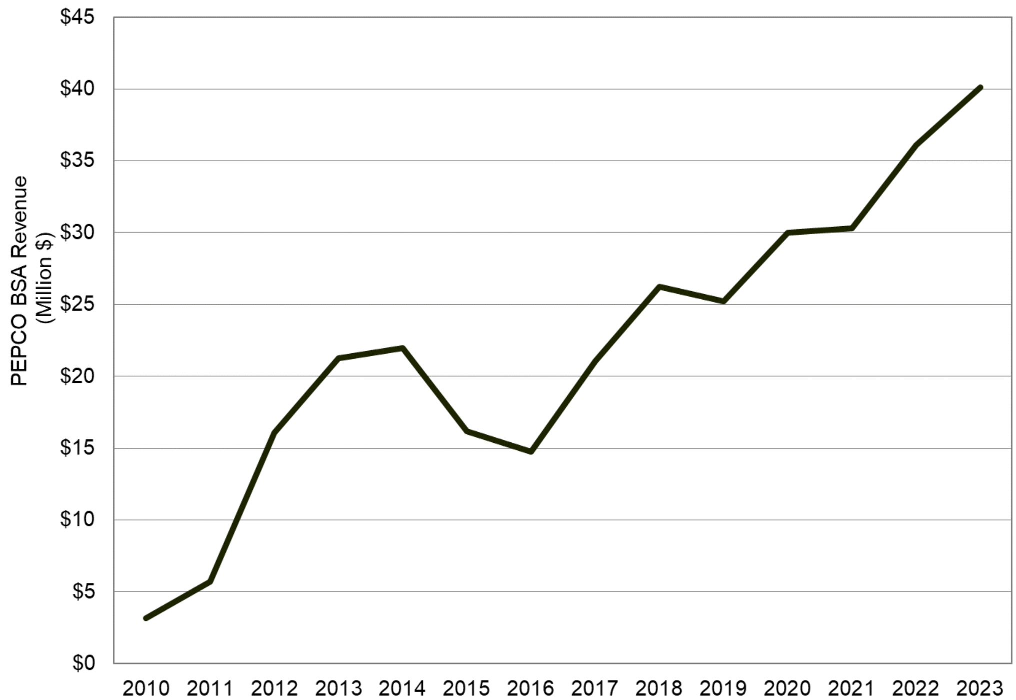

Figure 7: Historic Total BSA Revenues

Q. HAVE THE LEVEL OF SURCHARGES AND REFUNDS BEEN COMPARABLE SINCE THE BSA WAS PUT INTO PLACE?

A. No. Between 2009 and 2011, the Company collected total revenues (across all customer classes) in excess of its benchmark on eight different months (32 percent of the time). However, in the 139 months since 2011 (i.e., January 2012 – July 2023), the Company has reported a net revenue surplus (for all customer classes) in only one month.

Q. HAVE YOU REVIEWED HISTORIC BSA CREDITS AND DEBITS BY RATE CLASS?

A. Yes. Exhibit OPC (A)-15 provides historic BSA revenue balances by rate class and year since 2009. This analysis shows that very little of the Company's revenue volatility stems from residential customers. In fact, less than $19.6 million (6.7 percent) of the overall $294 million in BSA shortfalls can be attributable to residential customers. Most of the BSA shortfalls can be attributed to time metered general service ("GT") rate classes to the tune of $268.9 million, as well as the GT-LV rate class totaling $144.0 million.

Q. HAVE YOU EXAMINED THE COMPANY'S CUSTOMER COUNT AND USAGE BY RATE SCHEDULE?

A. Yes. Exhibit OPC (A)-16 provides historic use per customer ("UPC") by rate class and year since 2010. Most major Company rate classes have seen declining UPC in recent years. For example, estimated residential UPC for the Company has fallen from 0.64 MWh per year in 2010 to 0.62 MWh per year in 2022, a decrease of approximately 2.1 percent. This decline in UPC is even more noticeable for commercial customers, with estimated UPC for the GT-LV and MGT-LV class falling from 149.55 MWh per year in 2010 to 94.56 MWh per year, a decrease of 36.8 percent. However, the Company has seen its residential customer counts grow from 2.79 million to 3.6 million a 30.7 percent growth over this same time period while GT-LV and MGT-LV customer counts have grown by 39.4 percent during the same period. These new customers have offset the reduction in Company sales of electricity caused by falling UPC.

Q. HOW DOES THIS INFORMATION IMPACT THE OPERATIONS OF THE BSA?

A. These are important facts the Commission should consider in evaluating, as a policy matter, whether the BSA should be continued. While the BSA was originally implemented as a revenue decoupling mechanism to insulate the Company from changes in revenues due to a variety of factors including weather and increased energy efficiency, the mechanism now effectively operates as an attrition adjustment to insulate the Company from declining electric use primarily by GT rate class customers. In fact, the Company has admitted as much in a past proceeding before the Commission, claiming that the rationale supporting the continued use of the BSA has likely increased since the mechanism was originally approved.[168] Specifically the Company noted in part that its total energy consumption has been declining over the past decade, increasing the likelihood that the Company will be unable to recover Commission-approved cost of service without the BSA.[169] However, the purpose of the BSA was not to serve as an attrition adjustment but to move the District's energy efficiency initiatives forward.

B. BSA Deferrals and Prior Billing Determinant Error

Q. HOW ARE BILLING DETERMINANTS USED IN THE RATEMAKING PROCESS?

A. Billing determinants are customer data recorded in billing records, such as customer usage information and customer counts. This information is used both to bill customers and to develop future individual rates for utility service during rate cases. Incorrect billing determinants can lead to inaccurate billing. Errors in the internal reporting of billing information can lead to development of inaccurate rates during rate case proceedings, since

168 *See* Exhibit OPC (A)-32, *Formal Case No. 1139*, Exhibit PEPCO (L) (Chamberlin) at 11:20-22.

169 *Id.* at 6:9-12.

the amount of revenue expected to be generated from a developed tariff (rate) will be inaccurate.

Q. PLEASE EXPLAIN THE NATURE OF PEPCO'S BILLING DETERMINANTS ERROR AND ITS RELATIONSHIP WITH THE BSA.

A. The Company has previously stated that the demand billing determinants used in Formal Case Nos. 1139 and 1150 were "generally over-stated in the applicable test periods."[170] According to the Company, this billing determinant error resulted in an under-recovery of revenue that the Company then partially recovered through the operations of its BSA.[171] This means that demand rates for applicable rate classes were incorrectly established for the period between when approved rates resulting from Formal Case No. 1139 were effective (August 2017) until modified rates resulting from Formal Case No. 1156 were effective (July 2021).

Q. WHEN DID THE COMPANY FIRST NOTIFY PARTIES AND THE COMMISSION ABOUT ITS BILLING DETERMINANT ERROR?

A. The Company filed rebuttal testimony in Formal Case No. 1156 on April 8, 2020, to address issues raised by OPC[172] and AOBA[173] regarding the BSA and particularly its application to commercial customers taking service on Schedules MGTLV and GTLV. These two customer classes repeatedly reported consistently large under-recoveries of their class-specific authorized revenues, indicating a potential BSA-related problem. The

---

[170] *Formal Case No. 1156*, Exhibit PEPCO (4F) (Blazunas) at 17:19-21.

[171] *Id.* at 18:1-7; *see also Formal Case No. 1156*, Exhibit OPC (5A)-3.

[172] *See Formal Case No. 1156*, Exhibit OPC (A) (Dismukes) at 57.

[173] *See Formal Case No. 1156*, Exhibit AOBA (A) (B. Oliver) at 17:1-4.

Company's rebuttal noted that it had "identified an issue that it believes has contributed to the accumulation of the deferred BSA balances for these two classes."[174] The Company at the time noted that it had addressed the identified issue and that the proposed MRP Pilot avoided the identified issue by using forecasted billing determinants.[175]

Q. DID THE COMPANY SUBSEQUENTLY REVISE THIS POSITION?

A. Yes. Nearly four months later, on July 28, 2020, the Company filed errata to portions of its rebuttal testimony in Formal Case No. 1156. The errata reversed the Company's prior position that the proposed MRP was unaffected by the historic demand billing determinant error.[176] Instead, the Company noted that forecasted demand billing determinants used to design MRP rates were calculated using load factors derived from actual billing determinants in the test year.[177] A few days later on July 31, 2020, the Company filed a third round of supplemental testimony addressing its July 28, 2020 errata filing. In its third supplemental testimony filing, the Company explained that currently effective base distribution rates (from the last base rate case) were designed utilizing incorrect actual demand billing determinants, resulting in billed distribution demand revenues that were lower than actually collected.[178] The incorrectly constructed rates resulted in larger monthly BSA adjustments for the demand rates for commercial customers, thus increasing

174 *Formal Case No. 1156*, Exhibit Pepco (4F) at 17:17-18.

175 *Formal Case No. 1156*, Exhibit Pepco (4F) at 18:9-14.

176 *Formal Case No. 1156*, Errata to Rebuttal Testimony of Company Witness Blazunas at 1, filed July 28, 2020.

177 *Id.*

178 *Formal Case No. 1156*, Exhibit PEPCO (6F) (Blazunas) at 4:20 to 5:2.

BSA deferral balances.[179] The Company estimated that the error resulted in an annual $12.7 million under-recovery, or $20.8 million in total for the period August 2018 through March 2020.[180] This supplemental testimony marked the first instance where Pepco acknowledged the likely full extent of the identified error's impact on historical rates.

Q. DID THE COMPANY LATER BRIEF PARTIES CONCERNING THE EXTENT OF THE BILLING DETERMINANT ERROR?

A. Yes. On September 10, 2020, the Company held a technical conference on Pepco's BSA-related billing determinant errors as required by the Commission in Order No. 20617.[181] At the conference, the Company explained that in February of 2020, it was made aware by an employee of a regulated utility affiliate (later identified as Atlantic City Electric and Delmarva Power),[182] that an error in an internal report the Company used to collect kW demand information "double counted" customer demand in instances where a rate change occurred in the middle of a month.[183] This double-counting error had the effect of inflating customer demand information that was also used by the Company in its design of rates in its prior base rate cases (Formal Case Nos. 1139 and 1150). Because of the double counting error, retail commercial demand charges were set at inappropriate levels resulting in

---

179 *Id.* at 5:6-8.

183 The Office of the People's Counsel Response to the September 10 Technical Conference and Renewal of the Joint Motion to Dismiss Pepco's MRP Enhanced Proposal, to Direct Withdrawal of Pepco's Rate Case Application, and for Additional Relief at 3; *see also Formal Case No. 1156,* Pepco Response to OPC Data Request No. 61-3 (Exhibit OPC (A)-34) (explaining that "the error is a demand billing determinant report that double counted demand in the months with a "time slice" (such as a month with a rate change). A 'time slice' occurs when there are multiple price values within a bill period, and that price is setup to be prorated within that period.")

consistent under-recoveries in the BSA.[184] At the time, the Company informed parties that the total impact of the billing determinant error through December 2020 would be approximately $30.3 million.[185]

Q. DID ANY RATE CLASS EXPERIENCE ADVERSE CUSTOMER RATE IMPACTS FROM THIS BILLING DETERMINANT ERROR?

A. Yes. Effectively all Pepco commercial customers taking service on rate schedules that include demand rates were negatively affected by the Company's double counting error. The Company's double counting error not only understated demand charges, and demand charge revenues, but likely overstated volumetric rates set in prior base rate cases in order to reconcile overall class revenues. This outcome likely resulted in a cross-subsidization between customers within the rate class since higher load factor ratepayers (i.e. lower demand relative to energy use) were incorrectly receiving discounted service while customers with lower load factors (i.e. higher demand relative to energy use) were being charged higher than intended rates.

Q. WHY DID THE COMPANY'S BILLING DETERMINANT ERROR RESULT IN THE ACCUMULATION OF SIGNIFICANT BSA DEFERRAL BALANCES?

A. The BSA includes a ratepayer protection provision that limits any change in volumetric surcharges (the rate per kWh) to no more than 10 percent; any amount over this 10 percent cap is deferred for recovery in future periods. The Company's double counting error likely

---

184 *Id.*

185 *Formal Case No. 1156*, Pepco Response to Staff Data Request No. 19-16 (Exhibit OPC (A)-35).

contributed significantly to the accrual, over this time period, of sizeable deferred BSA balances for the relevant commercial rate classes.

Q. HAS THE COMPANY PROPOSED TO TAKE ANY FISCAL RESPONSIBILITY FOR ITS DOUBLE COUNTING ERROR?

A. No. Pepco has not assumed any responsibility nor offered to shoulder or share in the responsibility for the revenue shortfall that resulted from its failure to accurately implement the BSA or catch its double counting error in a timely manner.[186]

Q. HAS THE COMPANY PROVIDE ANY ANALYSIS TO SUPPORT A CONCLUSION THAT ITS OPERATION OF THE BSA WAS PRUDENT DESPITE THE BILLING DETERMINANT ERROR?

A. No. Pepco was explicitly asked to provide all documents and analyses that it had prepared related to the prudent (1) administration of the BSA, (2) incurrence of BSA deferral balances related to erroneous billing determinants, and (3) recover of erroneous deferral balances caused by the erroneous billing determinants.[187] The Company provided no such documents or analyses.

Q. HAVE YOU EXAMINED BSA DEFERRAL BALANCES?

A. Yes. Figure 8 shows the growth in BSA deferral balances over time. Prior to 2017, the total deferral balance associated with the BSA was never greater than $6 million. However, since 2017 BSA deferral balances have continuously been greater than $6 million every

---

[186] *See Formal Case No. 1156*, Pepco Response to OPC Data Request No. 61-17 (Exhibit OPC (A)-36) (stating that "the BSA deferral balances appropriately represent amounts approved for collection by the Company but not yet billed.")

[187] Exhibit OPC (A)-37, Pepco Response to OPC Data Request 10-6.

month, and furthermore continue to grow. As of November 2023, the Company reported a total BSA deferral balance of more than $111 million.

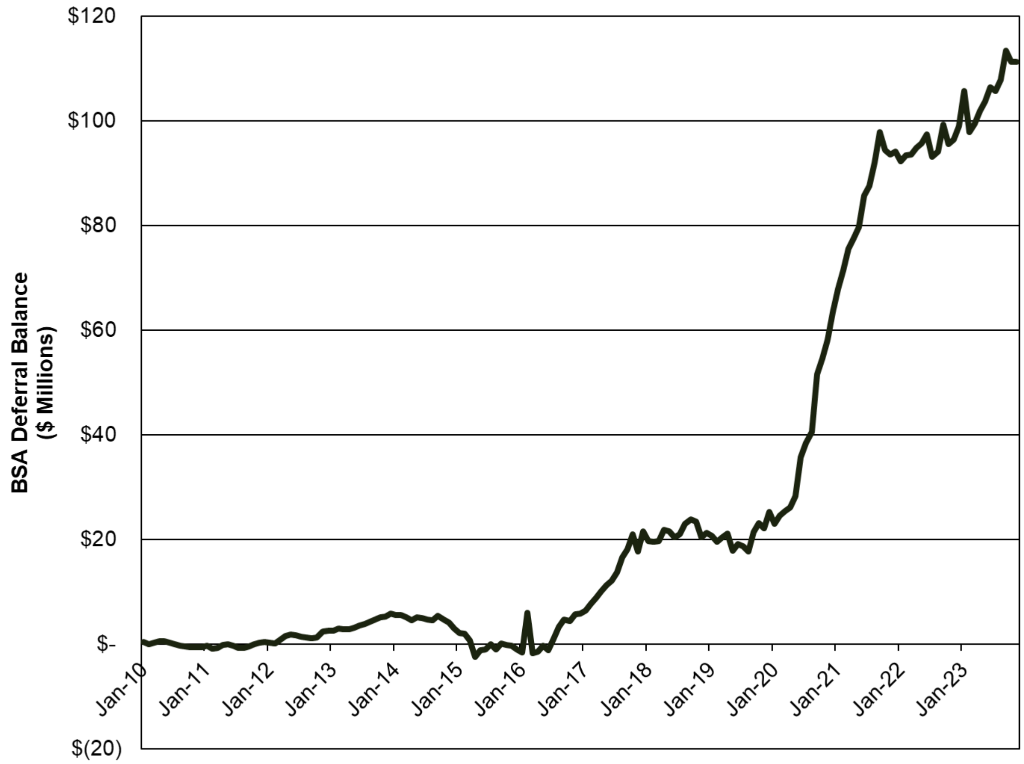

Figure 8: Historic Total BSA Deferral Balance

Q. DO RESIDENTIAL CUSTOMERS COMPRISE THE MAJORITY OF THESE DEFERRED BALANCES?

A. No. As shown in Figure 7, in the Company's November 2023 BSA filing all residential customers combined totaled $630,411 in BSA deferred balances of the total BSA deferred balance of more than $111 million. This means that residential customers comprised less than 0.6 percent (or six tenths of one percent) of the Company's total deferred BSA balance. The vast majority of deferred balances were associated with Timed General Services rate schedules, which combined totaled more than $108 million of the $111 million deferred balance. The GTLV rate schedule alone comprised nearly $87 million of the $111 million deferred balance.

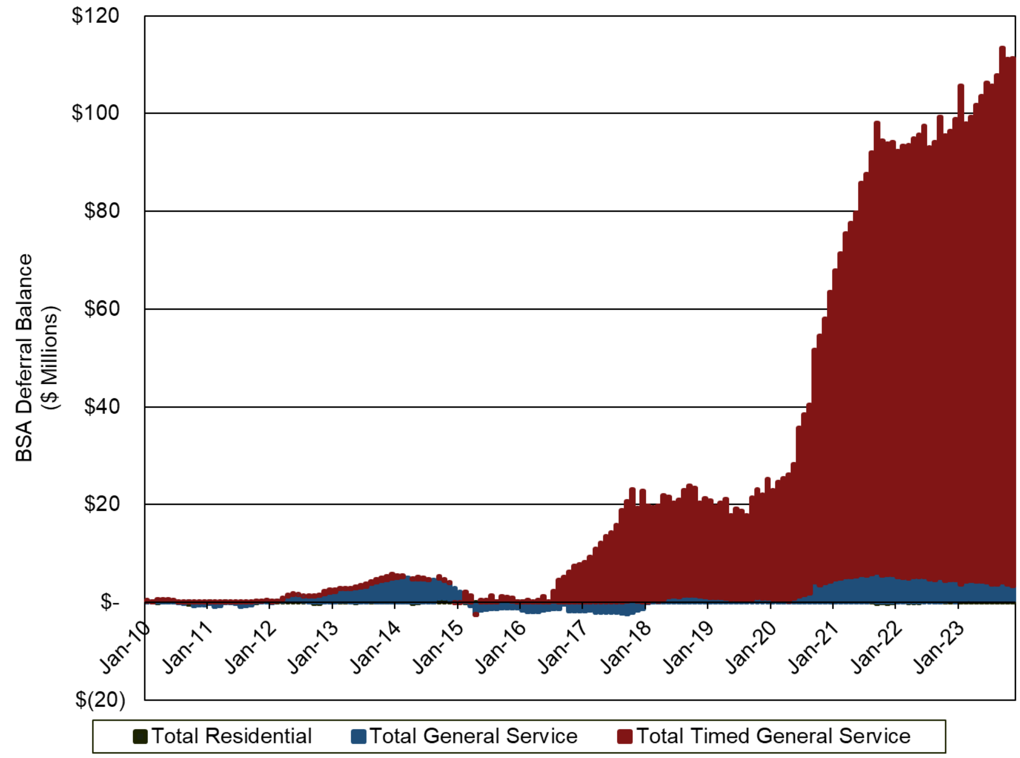

Figure 9: Historic Total BSA Deferral Balances by Customer Class

Q. HAVE YOU EXAMINED THE HISTORIC ACCURACY OF PEPCO'S DEMAND REPORTS?

A. Yes. Confidential Exhibit OPC (A)-17 estimates the impact of the Company's double counting error. The analysis shows notable impacts across various months, particularly in August 2018, the month in which rates approved in Formal Case No. 1150 become effective.[188] Confidential Exhibit OPC (A)-17 furthermore highlights the extent of Pepco's

---

188 *Formal Case No. 1156,* The Office of the People's Counsel Response to the September 10 Technical Conference and Renewal of the Joint Motion to Dismiss Pepco's MRP Enhanced Proposal, to Direct Withdrawal of Pepco's Rate Case Application, and for Additional Relief at 3.

mismanagement of the BSA since a cursory review of billing data should have raised concerns due to the extent of the Company's double counting mistake.

Q. DID COMMISSION STAFF HOST ANY TECHNICAL CONFERENCES REGARDING THE BSA AFTER THE CONCLUSION OF FORMAL CASE 1156?

A. Yes. Pursuant to Order No. 20755,[189] Commission Staff hosted three technical conferences after the conclusion of Formal Case No. 1156 which discussed structural deficiencies in the BSA and BSA deferments. The first of these was held November 19, 2021, the second was held December 9, 2021, while the third was held January 20, 2022.

Q. DID THE COMPANY DISCUSS ITS BSA DEFERRAL BALANCES AT ANY OF THESE TECHNICAL CONFERENCES?

A. Yes. At the second BSA technical conference, the Company updated parties on the status and causes of its BSA deferrals.[190] The Company confirmed that as of the end of October 2021, $98.5 million, or 99.72 percent, of the Company's BSA deferral balances were comprised of just four rate classes: GTLV ($55.2 million); MGTLV ($29.8 million); GT3A ($7.5 million); and GSLV ($5.7 million).[191] Furthermore, of the $98.5 million deferral balances at the time, the Company estimated that only $2.5 million would be recovered in the upcoming monthly BSA reconciliation, with the remaining $95.9 million being deferred to several months into the future.[192] The Company furthermore revealed that over

---

[189] *Formal Case No. 1156,* Order No. 20755 at ¶ 316.

[190] *Formal Case No. 1156,* "BSA Deferral Balances," Pepco Holdings presentation at Technical Workshop dated December 9, 2021.

[191] *Id.* at 13.

[192] *Id.*

the six year period from 2016 through 2021, it saw approximately $220 million in monthly BSA under-collections.[193]

Q. WHAT DRIVERS OF BSA COLLECTIONS DID THE COMPANY ANALYZE?

A. The Company analyzed five drivers of historic BSA under-collections – (1) changes in usage per customer ("UPC"); (2) changes in customer counts; (3) weather variation; (4) the previously noted billing determinant error; and (5) a normalization adjustment for the GTLV class in Formal Case No. 1150.[194] The Company furthermore estimated three sub-categories of changes in UPC including: changes in UPC due to the Covid-19 pandemic; changes in UPC due to District energy efficiency programs; and all other non-Covid-19 related causes of changes in UPC.[195]

Q. WHAT WERE THE RESULTS OF THE COMPANY'S ANALYSIS OF DRIVERS OF BSA UNDER-COLLECTIONS?

A. Exhibit OPC (A)-18 shows the results of the Company's analysis of historic BSA under-collections. The Company found that non-Covid-related changes in customer UPC accounted for the majority of historic BSA under-collections, comprising approximately 40 percent of historic BSA under-collections. The second largest driver was changes in customer UPC caused by the economic downturn resulting from the Covid-19 pandemic, which the Company estimated accounted for $48.2 million, or approximately 22 percent, of historic BSA under collections.

---

193 *Id.* at 21.

194 *Id.* at 20.

195 *Id.*

Q. DID THE COMPANY PROVIDE A REVISED ESTIMATE OF DOUBLE COUNTING ERRORS?

A. Yes. The Company, at the December 2021 technical conference, stated that its revised analysis of drivers of historic BSA under-collections found that its double counting error only resulted in $15.3 million in cumulative BSA under-collections over the five-year period from 2017 through 2021.[196] This represents a notable reduction in the Company's prior estimates of $20.8 million during the period from August 2018 through March 2020,[197] or the estimated $30.3 million the Company claimed would raise through December 2020.[198]

Q. HOW DID THE COMPANY EXPLAIN THESE CHANGING ESTIMATES?

A. The Company stated that, upon further analysis, its prior double counting error estimates were inclusive of two separate regulatory errors arising from Formal Case Nos. 1136 and 1150.[199] The first being the previously discussed billing determinant mistake and the second being a "normalization adjustment" for the GTLV class that was included in Formal Case No. 1150.[200] The Company estimated that this second normalization adjustment resulted in total BSA under collections of $20.3 million over the four year period from

---

200 *Id.*

2018 through 2021.[201] Combined, the Company estimated regulatory errors of $35.6 million in BSA under collections through June 2021.[202].[203]

Q. EXPLAIN THE GTLV NORMALIZATION ADJUSTMENT?

A. In final negotiations to develop a Settlement Agreement between parties to Formal Case No. 1150, Pepco and AOBA agreed to a normalization adjustment of the GTLV rate class. OPC was not involved in this discussion since it applied to the GTLV and not residential or small commercial rate classes. However, it is my understanding that this adjustment was intended to account for expected customer growth in the GTLV rate class based on historic trends.[204] However, it because apparent later, after the settlement, that the Company was seeing far fewer new GTLV customers than it anticipated, causing an estimated $12.3 million shortfall in annual GTLV annual revenues at the time.[205]

Q. HAS ANY OTHER PARTY EXAMINED THE DRIVERS OF THE COMPANY'S LARGE BSA UNDER-COLLECTIONS AND DEFERRED BALANCES?

A. Yes. In Order No. 20755, the Commission directed that an independent audit be conducted.[206] Atrium Economics ("Atrium") was selected as the Commission's independent auditor and issued its Final Report on July 7, 2023.[207] As part of their analysis,

---

201 *Id.*

203 The date at which these mistakes were removed, coincident with the effective date of new retail rates arising from Formal Case No. 1156

204 *See Id.* at 37, and *Formal Case No. 1150,* Exhibit PEPCO (3E)-1 at 10; interestingly this normalization adjustment was inaccurately labelled a "weather normalization" adjustment to GTLV customer counts in Pepco's Settlement Testimony exhibits in Formal Case No. 1150.

205 *Formal Case No. 1150*, Motion to Clarify at ¶ 4.

206 *Formal Case No. 1156*, Order No. 20755, at ¶ 316.

207 *Formal Case No. 1156*, "Pepco DC Bill Stabilization Adjustment Audit Report," (July 7, 2023).

Atrium evaluated Pepco's BSA deferral drivers analysis presented to parties at the December 2022 technical conference.[208]

Q. WHAT WERE THE FINDINGS OF THE ATRIUM REPORT REGARDING THE DRIVERS OF HISTORIC BSA UNDER-COLLECTIONS?

A. Atrium found that the billing determinant error was isolated to Case No. 1150[209] and did not extend to Case No. 1139 as represented by the Company in both Formal Case No. 1156 and during the December 2022 Technical Conference. Atrium, however, did largely confirm the Company's estimated BSA under-collections caused by the double counting mistake. Specifically, Atrium estimated that the impact of the mistake was $15.1 million (compared to the Company's estimated $15.3 million presented to parties at the December 2022 Technical Conference) over the four-year period 2018 through 2021.[210] Atrium also found that the Company significantly under-estimated the impact of the Formal Case No. 1150 GTLV normalization adjustment by only accounting for the error in demand charges caused by the adjustment without also accounting for the similar error in volumetric charges. Atrium found that the Formal Case No. 1150 GTLV normalization adjustment caused $27.1 million in BSA under-collections (compared to the Company's estimated $20.3 million presented to parties at the December 2022 Technical Conference).[211] Combined, Atrium found that the two regulatory errors accounted for $42.2 million in BSA under-collections.

---

208 *Id.* at 32.

209 *Id.* at 36-37.

210 *Id.* at 37.

211 *Id.* at 48.

Q. HAS PEPCO RESPONDED TO CONCERNS RAISED BY PARTIES AFTER REVIEW OF THE ATRIUM REPORT?

A. Yes. In recent Reply Comments responding to parties criticism of its administration of the BSA, Pepco claims that it has "consistently administered and executed the BSA in the manner approved by the Commission since the mechanism's inception,"[212] and that a large portion of deferred BSA balances are caused by the fact that billing determinants change between rate cases.[213] The Company highlights its current billing determinants used in BSA reconciliations which are based off of forecasts using data that is more than five years old.[214]

Q. DO YOU AGREE THAT THE COMPANY HAS IDENTIFIED A VALID CONCERN?

A. No. The Commission should recognize that Pepco has full control over when it decides to file base rate cases with the Commission. Indeed, the staleness of existing billing determinates from its Formal Case No. 1156 filing emphases the inappropriateness of the Company's proposed MYP in the context of rapidly changing customer base.

Q. WHAT IS YOUR CONCLUSION REGARDING THE PRESENCE OF LARGE BSA DEFERRAL BALANCES?

---

212 *Formal Case No. 1156*, Reply Comments of Potomac Electric Power Company on Atrium Final Report at page 8.

213 *Id.*

214 *Id.*

A. The current large BSA deferral balances demonstrate a major problem associated with the current BSA: that is, the mechanisms allow the Company to recovery any revenue deficiency regardless of the rationale for that shortcoming, up to and including Company created-double counting errors. The BSA also allows for the recovery of lost revenues resulting from economic contractions such as those associated with the Covid-19 pandemic. The BSA has the effect of reducing incentives for the Company to closely monitor its billing practices since it suffers no financial harm if such practices are in error, as evidenced by the large deferrals arising from the various Company errors identified in the Atrium Report.

C. Proposed Changes to the BSA Mechanism

Q. HAS THE COMMISSION EVER DISCUSSED THE APPROPRIATENESS OF THE BSA?

A. Yes, in Formal Case 1156. The Commission acknowledged at the time that the BSA protects Pepco from **any** difference between actual versus forecasted sales on a per-customer basis regardless of the source.[215] However, the Commission ultimately stated that it was not persuaded by parties to eliminate the BSA, in part, because such mechanisms continue to be credit-positive features that help the Company maintain its investment grade credit rating. The Commission, furthermore, noted that it shared parties concerned regarding the operations of the BSA – including the significant BSA deferrals – and noted its view that the BSA could be improved.[216] The Commission, thus, ordered the convening

---

215 *Formal Case No. 1156*, Order 20755, ¶ 314.

216 *Id.*, ¶ 315.

of technical conferences previously discussed to explore possible reforms of the BSA to address revenue pressures unrelated to the Company's energy efficiency efforts.[217]

Q. DOES THE COMPANY PROPOSE ANY CHANGES TO THE BSA IN THE CURRENT PROCEEDING?

A. Yes. In response to discussions with stakeholders through the BSA technical conferences, and its own research into decoupling best practices from other states, the Company proposes a series of four "enhancements" to better align the BSA with its proposed MYP.[218] These include: (1) a change in the structure of the BSA from RPC targets to flat class revenue targets; (2) a change in the structure of the BSA from monthly reconciliations and surcharges to an annual process; (3) incorporation of demand surcharges for demand-metered classes; and (4) displaying of BSA surcharges as separate line items on customer bills.[219]

Q. WHY DOES THE COMPANY PROPOSE TO CHANGE FROM AN RPC BSA TO A TOTAL CLASS REVENUE BSA?

A. The Company states that there are two notable limitations associated with the current BSA revenue target structure. First, the Company states that the RPC structure assumes that any new customer added to a rate class will have approximately the same cost of service as the class average customers.[220] This assumption is problematic for large commercial classes

---

217 *Id.*, ¶ 316.

218 *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 60:4-9.

219 *Id.* at 61:5-11.

220 *Id.* at 62:3-5.

with fewer customer counts and greater customer load diversity.[221] The Company further states that, to the extent new customers have lower cost of service than class average, the existing BSA RPC framework has the potential to exacerbate existing interclass subsidies.[222] Second, the Company notes that under an MYP ratemaking structure the Company's rates and revenue requirement are based on forecasted data which includes expected customer and cost of service growth.[223]

Q. WHY DOES THE COMPANY PROPOSE TO MOVE FROM MONTHLY TO ANNUAL BSA SURCHARGE FILINGS?

A. The Company states that the current monthly BSA structure has introduced high degrees of customer bill volatility[224] which, interestingly, contravenes one of the oft-cited reasons for adopting revenue decoupling by utilities (i.e., reducing ratepayer bill volatility and increasing revenue stability)[225] and indeed the "stability" nature of the BSA. For example, the Company notes that Schedule GT 3B has only one customer, which means that rate schedule can sometime appear to have a significant under-recovery of 100 percent in a given month to be followed by significant over-recovery or 200 percent the next depending on billing cycles relative to calendar months.[226]

---

221 *Id.* at 62:5-8.

222 *Id.* at 62:11-13.

223 *Id.* at 62:14-18.

224 *Id.* at 63:7-10.

225 *See*, *Formal Case No. 1053*, Order No. 15556, ¶ 5, citing *Formal Case No. 1053*, Exhibit Pepco (H) at 18.

226 *Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 63:10-14.

Q. WHY DOES THE COMPANY PROPOSE TO IMPLEMENT DEMAND-BASED BSA SURCHARGE RATES FOR DEMAND-METERED CLASSES?

A. The existing BSA currently is designed as a volumetric dollar-per-kWh charge for all rate classes. The Company is concerned that this structure can lead to intraclass equity concerns by shifting revenue responsibility towards high load factor customers from low load factor customers without a rate class.[227]

Q. WHY DOES THE COMPANY PROPOSE TO IMPLEMENT NEW BSA SURCHARGES AS A SEPARATE LINE ITEM ON CUSTOMER'S MONTHLY BILL?

A. The existing BSA surcharge is not implemented as a separate line item on customers' monthly bill, and instead is aggregated within a single "Energy Charge" line item with other volumetric charges. In the interest of addressing parties' concerns about the lack of transparency, the Company proposes to separate the BSA surcharge onto a separate line item going forward.[228]

D. Proposed Rate Base Accounting for Deferred Balances

Q. DID THE COMPANY INCLUDE ANY ADDITIONAL RECOMMENDATIONS REGARDING THE BSA IN ITS TTYCF?

A. Yes. While not included in its MYP case-in-chief, the Company in its TTYCF requested that the Commission approve the establishment of a regulatory asset that would allow the

---

[227] *Id.* at 65:14-20.

[228] *Id.* at 66:14-18.

Company to include BSA deferred balances in rate base for its proposed TTYCF.[229] Specifically, the proposed regulatory asset and ratemaking adjustment would increase the Company's test year rate base by nearly $113.8 million, reflecting the estimated BSA deferred balance on December 31, 2023.[230]

Q. WHAT IS THE COMPANY'S RATIONALE FOR INCLUDING THE PROPOSED BSA REGULATORY ASSET?

A. The Company notes that Atrium recommended in its report that the Commission continue to monitor Pepco's credit quality for signs of deterioration and consider implementing credit support measures such as allowing a return on BSA deferral balances.[231] The Company states that the current large BSA deferral balance put additional cash flow burdens on the Company and negatively impacts its earned ROE.[232] The Company did not propose such a measure in its MYP rate case proposal since Pepco's proposed MYP and updated billing determinants will improve the overall financial health of the Company.[233]

E. BSA Recommendations

Q. WHAT ARE YOUR RECOMMENDATIONS REGARDING THE COMPANY'S BSA?

---

[229] *Formal Case No. 1176*, Exhibit PEPCO (3A)-1, Additional Supplemental Direct Testimony of Elizabeth M. D. O'Donnell at 5:9-12.

[230] *Formal Case No. 1176*, Exhibit PEPCO (2B)-1.

[231] *Formal Case No. 1176*, Exhibit PEPCO (3A)-1, Additional Supplemental Direct Testimony of Elizabeth M. D. O'Donnell at 4:14-18.

[232] *Id.* at 5:3-12.

[233] *Id.*

A. I recommend the BSA be discontinued. The BSA is not functioning as intended. The BSA allows the Company to recover revenues shortfalls regardless of the source, and therefore inherently reduces incentives for the Company to prudently manage its operations and insulates the Company from a wide range of business risk that can include the economic contraction caused by the Covid-19 pandemic. Furthermore, to the extent the Commission approves the Company's proposed MYP, even the Company recognizes that elements of the BSA are now duplicative of elements of the MYP.[234] Specifically, the proposed MYP is based off forecasted billing determinants such as forecasted customer counts and volumetric sales, and thus is already designed to reflect forecasted changes in customer usage.

Q. HAS THE COMMISSION RECENTLY EXPRESSED CAUTION REGARDING THE USE OF REVENUE DECOUPLING BY JURISDICTIONAL UTILITIES?

A. Yes. The Commission recently rejected a WGL revenue decoupling proposal offered in its last base rate case.[235] The Commission noted that it is currently considering possible reform of Pepco's BSA and that approval of WGL's revenue decoupling proposal would be inappropriate. The Commission identified specific issues with the Pepco decoupling mechanism including: (a) how Pepco's BSA impacts ratepayers; (b) whether the BSA insulates Pepco's revenues from the impact of weather and economic changes as well as

---

[234] *Id.* at 62:14-18.

[235] Order No. 21939 at ¶ 370.

reducing a utility's disincentive for energy efficiency; and (c) how Pepco's BSA will interact with future electrification efforts.[236]

Q. DO YOU HAVE AN ALTERNATIVE RECOMMENDATION IF THE COMMISSION DECIDES TO RETAIN THE BSA?

A. Yes. Elsewhere, I have recommended that the Commission not extend the Company's MYP. If the Commission does not accept this MYP recommendation, or, if for any other reason, the Commission decides to retain the BSA, I recommend adoption of the Company's proposed BSA modifications. These proposed BSA modifications will reduce several known problematic elements of the BSA including the mechanism's problematic monthly reconciliations, which produces clearly anomalous BSA adjustments for small commercial rate classes, and the current RPC framework which unnecessarily adds complexity to the mechanism while allowing Company revenues to increase beyond those approved in prior base rates.

Q. WHAT IS YOUR RECOMMENDATION REGARDING THE COMPANY'S PROPOSED RATE BASE TREATMENT OF BSA DEFERRED BALANCES?

A. I recommend the Commission reject the Company's proposal to include its test year BSA deferred balance as an element of rate base, allowing the Company to earn a rate of return on this balance. The Company in the current proceeding notes several structure concerns associated with the calculations of existing BSA surcharges.[237] However, even ignoring the Company's admitted billing determinant error which has contributed to the significant

---

[236] *Id.*

[237] *See Formal Case No. 1176*, Exhibit PEPCO (E) (Bonikowski) at 61:3-10.

growth in these deferred balances over the past few years, the Commission should recognize that the Company had the opportunity to request changes to the BSA operations at any point in the mechanism's 14-year history. Accepting the Company's request to include BSA deferred balances as part of rate base would effectively reward Pepco for not exercising appropriate oversight of BSA operations.

Q. DO YOU HAVE A RECOMMENDATION REGARDING THE CURRENT LARGE BSA DEFERRAL BALANCES FOR COMMERCIAL RATE CLASSES?

A. Yes. I recommend that the Commission recognize the portion of BSA deferral balances associated with the Company's past administrative errors be disallowed from recovery by retail customers. The BSA mechanism should not function to immunize the Company from its own mistakes.

Q. HAS THE COMMISSION PREVIOUSLY RECOGNIZED THE IMPORTANCE OF HOLDING PEPCO ACCOUNTABLE FOR ITS OWN MISTAKES?

A. Yes. The Commission earlier this year found that Pepco is currently or has been in violation of relevant laws and regulations pertaining to the installation of Community Renewable Energy Facility ("CREF") meters.[238] The Commission declined to impose any financial penalties on the Company and give "Pepco the benefit of the doubt that its flawed reading of the law and [the Commission's] regulations [were] not a deliberate attempt to undermine them."[239] However, the Commission also made it clear that the Commission's decision to not establish a direct financial penalty shielded it from bearing the

---

[238] *Formal Case No. 1171*, Order No. 21649 at ¶ 3, citing Order No. 21600 at ¶ 1.

[239] *Formal Case No. 1171*, Order No. 21649 at ¶ 9.

consequences of its own erroneous reading of relevant laws and regulations, and that Pepco should not be allowed to dump these consequences on the backs of ratepayers.[240]

> In Order No. 21600, we declined to impose a financial penalty because we gave Pepco the benefit of the doubt that its flawed reading of the law and our regulations was not a deliberate attempt to undermine them. **However, the fact that we saw no reason to punish Pepco with a financial penalty does not create a shield against a claim that Pepco should be prohibited from dumping the consequences of the Company's error onto the backs of ratepayers.** When it comes to assigning costs to ratepayers, Pepco must first show that the shift in costs is just and reasonable and that showing has not, and cannot, be made (at least under these circumstances).[241]

Q. HAVE YOU ESTIMATED THE SPECIFIC BSA DEFERRAL BALANCES TO BE REMOVED FROM RATE RECOVERY?

A. Yes. Exhibit OPC (A)-19 presents detailed calculations of rate-specific BSA deferral balances to be removed from rate recovery. These calculations are based on the findings of the Atrium Report estimates of the impact of the Formal Case No. 1150 billing determinant mistake and GTLV normalization adjustment. In total, I recommend that $42.2 million of BSA deferral balance be removed from ratepayer recovery, including $19.3 million from the GTLV rate class and $20.1 million from ratepayer recovery for the MGTLV rate class.

Q. DO YOU HAVE ANY ADDITIONAL RECOMMENDATION REGARDING BSA DEFERRAL BALANCES?

---

240 *Id.*

241 *Id.*, emphasis added.

A. Yes. The Atrium Report found that approximately 25 percent of BSA deferral balances, totaling $69.5 million, are due to revenue under-recoveries resulting from the effects of the Covid-19 pandemic.[242] The Commission should consider alternative recovery options for these balances outside of the BSA, including inclusion of these Covid-related balances within the proposed regulatory asset for pandemic-related expenses.[243]

IX. CONCLUSIONS AND RECOMMENDATIONS

Q. WHAT IS YOUR RECOMMENDATION REGARDING THE COMPANY'S PROPOSED REVENUE DISTRIBUTION?

A. I recommend that the Commission reject the Company's proposed revenue distribution, which places an increase of 2.3 times the system average on residential ratepayers. Until the Commission can receive assurances that increasing residential revenue responsibility will improve its relative rate of return, I recommend the Commission reevaluate its policy of eliminating negative class rates of return. Instead, the Commission should adopt a more reasonable increase to currently underearning classes equal to 1.25 times the overall system average.

Q. WHAT ARE YOUR CUSTOMER CHARGE RECOMMENDATIONS AND CONCLUSIONS?

A. I recommend that the Commission direct the Company to maintain customer charges at their current levels.

---

242 *Formal Case No. 1156*, "Pepco DC Bill Stabilization Adjustment Audit Report," (July 7, 2023) at 50.

243 *Formal Case No. 1176*, Exhibit PEPCO (B) (Leming) at 61:11-13.

Q. WHAT ARE YOUR CONCLUSIONS REGARDING THE COMPANY'S PROPOSED MYP?

A. I recommend that the Commission reject the Company's requested MYP. There is no evidence to support a finding that the Company's MRP pilot provided any net public benefits or was in the public interest. The Company has provided no detailed information in this proceeding to support claims that this proposal would produce those benefits or advance the public interest.

Q. WHAT ARE YOUR RECOMMENDATIONS REGARDING THE COMPANY'S BSA?

A. I recommend the BSA be discontinued, as it is not functioning as intended. Moreover, should the Commission approve a multiyear plan, the BSA should be discontinued as it is duplicative of elements in a multiyear plan. Specifically, the proposed MYP is based off forecasted billing determinants such as forecasted customer counts and volumetric sales, and thus is already designed to reflect forecasted changes in customer usage.

Q. DO YOU HAVE AN ALTERNATIVE RECOMMENDATION IF THE COMMISSION DECIDES TO RETAIN THE BSA?

A. Yes. If for any reason the Commission decides to retain the BSA, I recommend adoption of the Company's proposed BSA modifications.

Q. WHAT IS YOUR RECOMMENDATION REGARDING THE COMPANY'S PROPOSED RATE BASE TREATMENT OF BSA DEFERRED BALANCES?

A. I recommend the Commission reject the Company's proposal in its TTYF of including the BSA deferred balance in the rate base. This would unfairly allow the Company to earn a rate of return on this balance, which solely stems from its own imprudence.

Q. DO YOU HAVE A RECOMMENDATION REGARDING THE CURRENT LARGE BSA DEFERRAL BALANCES FOR COMMERCIAL RATE CLASSES?

A. Yes. I recommend that the Commission recognize the portion of BSA deferral balances associated with the Company's past administrative errors be disallowed from recovery by retail customers. The BSA mechanism should not function to immunize the Company from its own mistakes.

Q. DO YOU HAVE ANY ADDITIONAL RECOMMENDATION REGARDING BSA DEFERRAL BALANCES?

A. Yes. I recommend that the Commission consider alternative recovery options for Covid-19 related BSA deferral balance outside of the BSA, including inclusion of these Covid-related balances within the proposed regulatory asset for pandemic-related expenses.

Q. DOES THIS CONCLUDE YOUR DIRECT TESTIMONY?

A. Yes.

42. *The Benefits of Continued and Expanded Investments in the Port of Venice*. (2009). With Christopher Peters and Kathryn Perry. Baton Rouge, LA: LSU Center for Energy Studies. 83 pp.

43. *Examination of the Development of Liquefied Natural Gas on the Gulf of Mexico*. (2008). U.S. Department of the Interior, Minerals Management Service, Gulf of Mexico OCS Region, New Orleans, LA OCS Study MMS 2008-017. 106 pp.

44. *Gulf of Mexico OCS Oil and Gas Scenario Examination: Onshore Waste Disposal*. (2007). With Michelle Barnett, Derek Vitrano, and Kristen Strellec. OCS Report, MMS 2007-051. New Orleans, LA: U.S. Department of the Interior, Minerals Management Service, Gulf of Mexico Region.

45. *Economic Impact Analysis of the Proposed Lake Charles Gasification Project*. (2007). Report Prepared on Behalf of Leucadia Corporation.

46. *The Economic Impacts of New Jersey's Proposed Renewable Portfolio Standard.* (2005) Report Prepared on Behalf of the New Jersey Division of Ratepayer Advocate.

47. *The Importance of Energy Production and Infrastructure in Plaquemines Parish*. (2006). Report Prepared on Behalf of Project Rebuild Plaquemines.

48. *Louisiana's Oil and Gas Industry: A Study of the Recent Deterioration in-State Drilling Activity*. (2005). With Kristi A.R. Darby, Jeffrey M. Burke, and Robert H. Baumann. Baton Rouge, LA: Louisiana Department of Natural Resources.

49. *Comparison of Methods for Estimating the NO_x Emission Impacts of Energy Efficiency and Renewable Energy Projects Shreveport, Louisiana Case Study*. (2005). With Adam Chambers, David Kline, Laura Vimmerstedt, Art Diem, and Dmitry Mesyanzhinov. Golden, Colorado: National Renewable Energy Laboratory.

50. *Economic Opportunities for a Limited Industrial Retail Choice Plan in Louisiana*. (2004). With Elizabeth A. Downer and Dmitry V. Mesyanzhinov. Baton Rouge, LA: Louisiana State University Center for Energy Studies.

51. *Economic Opportunities for LNG Development in Louisiana*. (2004). With Elizabeth A. Downer and Dmitry V. Mesyanzhinov. Baton Rouge, LA: Louisiana Department of Economic Development and Greater New Orleans, Inc.

52. *Marginal Oil and Gas Production in Louisiana: An Empirical Examination of State Activities and Policy Mechanisms for Stimulating Additional Production*. (2004). With Dmitry V. Mesyanzhinov, Jeffrey M. Burke, Robert H. Baumann. Baton Rouge, LA: Louisiana Department of Natural Resources, Office of Mineral Resources.

53. *Deepwater Program: OCS-Related Infrastructure in the Gulf of Mexico Fact Book.* (2004). With Louis Berger Associates, University of New Orleans National Ports and Waterways Institute, and Research and Planning Associates. MMS Study No. 1435-01-99-CT-30955. U.S. Department of the Interior, Minerals Management Service.

54. *The Power of Generation: The Ongoing Benefits of Independent Power Development in Louisiana.* With Dmitry V. Mesyanzhinov, Jeffrey M. Burke, and Elizabeth A. Downer. Baton Rouge, LA: LSU Center for Energy Studies, 2003.

55. *Modeling the Economic Impact of Offshore Oil and Gas Activities in the Gulf of Mexico: Methods and Application.* (2003). With Williams O. Olatubi, Dmitry V. Mesyanzhinov, and Allan G. Pulsipher. Prepared by the Center for Energy Studies, Louisiana State University, Baton Rouge, LA. OCS Study MMS2000-0XX. U.S. Department of the Interior, Minerals Management Service, Gulf of Mexico OCS Region, New Orleans, LA.

56. *An Analysis of the Economic Impacts Associated with Oil and Gas Activities on State*

Leases. (2002) With Robert H. Baumann, Dmitry V. Mesyanzhinov, and Allan G. Pulsipher. Baton Rouge, LA: Louisiana Department of Natural Resources, Office of Mineral Resources.

57. *Alaska In-State Natural Gas Demand Study*. (2002). With Dmitry Mesyanzhinov, et.al. Anchorage, Alaska: Alaska Department of Natural Resources, Division of Oil and Gas.

58. *Moving to the Front of the Lines: The Economic Impacts of Independent Power Plant Development in Louisiana*. (2001). With Dmitry Mesyanzhinov and Williams O. Olatubi. Baton Rouge, LA: Louisiana State University, Center for Energy Studies.

59. *The Economic Impacts of Merchant Power Plant Development in Mississippi.* (2001). Report Prepared on Behalf of the US Oil and Gas Association, Alabama and Mississippi Division. Houston, TX: Econ One Research, Inc.

60. *Energy Conservation and Electric Restructuring in Louisiana*. (2000). With Dmitry Mesyanzhinov, Ritchie D. Priddy, Robert F. Cope III, and Vera Tabakova. Baton Rouge, LA: Louisiana State University, Center for Energy Studies.

61. *Assessing the Environmental and Safety Risks of the Expanded Role of Independents in Oil and Gas E&P Operations on the U.S. Gulf of Mexico OCS.* (1996). With Allan Pulsipher, Omowumi Iledare, Dmitry Mesyanzhinov, William Daniel, and Bob Baumann. Baton Rouge, LA: Louisiana State University, Center for Energy Studies.

62. *Restructuring the Electric Utility Industry: Implications for Louisiana.* (1996). With Allan Pulsipher and Kimberly H. Dismukes. Baton Rouge, LA: Louisiana State University, Center for Energy Studies.

GRANT RESEARCH

1. *Co-Principal Investigator* (2022). With Gregory B. Upton, Jr. Estimating the benefits of electricity restoration to critical energy infrastructure. Funded by Entergy Corporation. Total Funding: $56,088. Status: Completed.

2. *Co-Principal Investigator*. (2021). With Gregory B. Upton Jr. Estimating the benefits of underground carbon dioxide storage investments. Funded by Gulf Coast Sequestration. Total Funding: $124,835. Status: In Progress.

3. *Principal Investigator*. (2021). Louisiana Greenhouse Gas Inventory Update and Report. Governor's Office of Coastal Affairs. Total Funding $65,830. Status: Completed.

4. *Principal Investigator*. (2021). Estimating Louisiana's power generation greenhouse gas emissions. The Nature Conservancy. Total Funding: $9,994. Status: Completed.

5. *Co-Principal Investigator*. (2021). With Gregory B. Upton. Estimating the economic impacts of methanol investments in St. James Parish. Koch Industries. Total Funding: $37,457. Status: Completed.

6. *Co-Principal Investigator*. (2019). With Gregory B. Upton Estimating the economic impact of TransCanada pipeline investments. TransCanada Pipelines. Total Funding: $40,798. Status: Completed.

7. *Co-Principal Investigator*. (2018). With Gregory B. Upton. Estimating the economic impact of Enable Pipeline Investments. Total Funding: $49,798. Status: Completed.

8. *Co-investigator*. Estimating offshore Gulf of Mexico carbon capture, sequestration, and utilization opportunities. (2018). With Southern States Energy Board, Advanced Resources International, Argonne Laboratories, University of Alabama, University of South Carolina, and Oklahoma State University. U.S. Department of Energy, National Energy Technology Laboratory. Total funding: $731,031 (LSU share of $4.0 million project, three years, in progress).

9. *Co-Principal Investigator*. Planning Grant: Engineering Research Center for Resiliency Enhancement and Disaster-Impact Interception ("READII") in the Manufacturing Sector. (2018). With Mahmoud El-Halwagi, Mark Stadtherr, Heshmat Aglan, Efstratos Postikopoulus. National Science Foundation (#1840512). Total Funding: $100,000 (one year). Status: Completed.

10. *Principal Investigator*. Understanding MISO long term infrastructure needs and stakeholder positions. (2017). Midcontinent Independent System Operator. Total Project: $9,500, six months. Status: Completed.

11. *Principal Investigator*. Offshore oil and gas activity impacts on ecosystem services in the Gulf of Mexico. (2017). With Brian F, Snyder. U.S. Department of the Interior, Bureau of Ocean Energy Management. Total Project: $240,982, two years. Status: Completed.

12. *Principal Investigator*. Economic Impacts of the Bayou Bridge pipeline. (2017). With Gregory B, Upton, Jr., Energy Transfer Corporation. $9,900. Status: Completed.

13. *Principal Investigator*. Integrated carbon capture, storage and utilization in the Louisiana chemical corridor. (2017). U.S, Department of Energy/National Energy Technology Laboratory. Total funding: $1,300,000 (18 months). Status: Completed.

14. *Co-Principal Investigator*. Gulf coast energy outlook and analysis. (2016). With Gregory B. Upton and Mallory Vachon. Regions Bank. Total funding: $20,000, one year. Status: Completed.

15. *Principal Investigator*. GOM energy infrastructure trends and factbook update. (2016). With Gregory B. Upton and Mallory Vachon. U.S. Department of the Interior, Bureau of Ocean Energy Management ("BOEM"). Total funding: $224,995, two years. Status: In progress.

16. *Principal Investigator*. Examining Louisiana's Industrial Carbon Sequestration Potential. Phase 2: Follow-up and estimation. (2016). With Brian F. Snyder. Southern States Energy Board. Total Project: $69,990, three months. Status: Completed.

17. *Principal Investigator*. Examining Louisiana's Industrial Carbon Sequestration Potential. Phase 1: Scoping and Identification. (2016). With Brian F. Snyder. Southern States Energy Board. Total Project: $29,919, three months. Status: Completed.

18. *Principal Investigator*. Energy efficiency building codes for Louisiana. (2016). With Brian F. Snyder. Louisiana Department of Natural Resources. Total Project: $50,000, one year. Status: Completed.

19. *Principal Investigator*. An update of Louisiana's combined heat and power potentials, current utilizations, and barriers to improved operating efficiencies. (2016). Louisiana Department of Natural Resources. Total Project: $90,000, one year. Status: Completed.

20. *Principal Investigator*. Combined Heat and Power Stakeholder Meeting. (2016). Southeastern Energy Efficiency Council. Total Project $9,160, two months. Status: Completed.

21. *Co-Investigator*. "Expanding Ecosystem Service Provisioning from Coastal Restoration to Minimize Environmental and Energy Constraints" (2015). With John Day and Chris D'Elia. Gulf Research Program. Total Project: $147,937. Status: Completed.

22. *Principal Investigator*. "Coastal Marine Institute Administrative Grant" (2104). U.S. Department of the Interior. Total Project $45,000. Status: Completed.

23. *Principal Investigator*. "Analysis of the Potential for Combined Heat and Power (CHP) in Louisiana." (2013). Louisiana Department of Natural Resources. Total Project: $90,000. Status: Completed.

24. *Co-Investigator*. "CNH: A Tale of Two Louisianas: Coupled Natural-Human Dynamics in a Vulnerable Coastal System" (2013) With Nina Lam, Margaret Reams, Kam-Biu Liu, Victor Rivera, Yi-Jun Xu and Kelley Pace. National Science Foundation. Total Project: $1.5 million. Status: Completed (Sept 2012-Feb 2017).

25. *Principal Investigator*. "Examination of Unconventional Natural Gas and Industrial Economic Development" (2012). America's Natural Gas Alliance. Total Project: $48,210. Status: Completed.

26. *Principal Investigator*. "Investigation of the Potential Economic Impacts Associated with Shell's Proposed Gas-To-Liquids Project" (2012). Shell Oil Company, North America. Total Project: $76,708. Status: Completed.

27. *Principal Investigator*. "Analysis of the Federal Wind Energy Production Tax Credit." American Energy Alliance. Total Project: $20,000. Status: Completed.

28. *Principal Investigator*. "Energy Sector Impacts Associated with the Deepwater Horizon Oil Spill." Louisiana Department of Economic Development. Total Project: approximately $50,000. Status: Completed.

29. *Principal Investigator*. "Economic Contributions and Benefits Support by the Port of Venice." Port of Venice Coalition. Total Project: $20,000. Status: Completed.

30. *Principal Investigator.* "Energy Policy Development in Louisiana." Louisiana Department of Natural Resources. Total Project: $150,000. Status: Completed.

31. *Principal Investigator.* "Preparing Louisiana for the Possible Federal Regulation of Greenhouse Gas Regulation." With Michael D. McDaniel. Louisiana Department of Economic Development. Total Project: $98,543. Status: Completed.

32. *Principal Investigator*. "OCS Studies Review: Louisiana and Texas Oil and Gas Activity and Production Forecast; Pipeline Position Paper; and Geographical Units for Observing and Modeling Socioeconomic Impact of Offshore Activity." (2008). With Mark J. Kaiser and Allan G. Pulsipher. U.S. Department of the Interior, Minerals Management Service.

Total Project: $377,917 (3 years). Status: Completed.

33. *Principal Investigator*. "State and Local Level Fiscal Effects of the Offshore Petroleum Industry." (2007). With Loren C. Scott. U.S. Department of the Interior, Minerals Management Service. Total Project: $241,216 (2.5 years). Status: Completed.

34. *Principal Investigator*. "Understanding Current and Projected Gulf OCS Labor and Ports Needs." (2007). With Allan. G. Pulsipher, Kristi A. R. Darby. U.S. Department of the Interior, Minerals Management Service. Total Project: $169,906. (one year). Status: Completed.

35. *Principal Investigator*. "Structural Shifts and Concentration of Regional Economic Activity Supporting GOM Offshore Oil and Gas Activities." (2007). With Allan. G. Pulsipher, Michelle Barnett. U.S. Department of the Interior, Minerals Management Service. Total Project: $78,374 (one year). Status: Awarded, Completed.

36. *Principal Investigator*. "Plaquemine Parish's Role in Supporting Critical Energy Infrastructure and Production." (2006). With Seth Cureington. Plaquemines Parish Government, Office of the Parish President and Plaquemines Association of Business and Industry. Total Project: $18,267. Status: Completed.

37. *Principal Investigator*. "Diversifying Energy Industry Risk in the Gulf of Mexico." (2006). With Kristi A. R. Darby. U.S. Department of the Interior, Minerals Management Service. Total Project: $65,302 (two years). Status: Awarded, Completed.

38. *Principal Investigator*. "Post-Hurricane Assessment of OCS-Related Infrastructure and Communities in the Gulf of Mexico Region." (2006). U.S. Department of the Interior, Minerals Management Service. Total Project Funding: $244,837. Status: Completed.

39. *Principal Investigator*. "Ultra-Deepwater Road Mapping Process." (2005). With Kristi A. R. Darby, Subcontract with the Texas A&M University, Department of Petroleum Engineering. Funded by the Gas Technology Institute. Total Project Funding: $15,000. Status: Completed.

40. *Principal Investigator*. "An Examination of the Opportunities for Drilling Incentives on State Leases." (2004). With Robert H. Baumann and Kristi A. R. Darby. Louisiana Office of Mineral Resources. Total Project Funding: $75,000. Status: Completed.

41. *Principal Investigator*. " An Examination on the Development of Liquefied Natural Gas Facilities on the Gulf of Mexico." (2004). With Dmitry V. Mesyanzhinov and Mark J. Kaiser. U.S. Department of the Interior, Minerals Management Service. Total Project Funding $101,054. Status: Completed.

42. *Principal Investigator*. "Examination of the Economic Impacts Associated with Large Customer, Industrial Retail Choice." (2004). With Dmitry V. Mesyanzhinov. Louisiana Mid-Continent Oil and Gas Association. Total Project Funding: $37,000. Status: Completed.

43. *Principal Investigator*. "Economic Opportunities from LNG Development in Louisiana." (2003). With Dmitry V. Mesyanzhinov. Metrovision/New Orleans Chamber of Commerce and the Louisiana Department of Economic Development. Total Project Funding: $25,000. Status: Completed.

44. *Principal Investigator*. "Marginal Oil and Gas Properties on State Leases in Louisiana: An Empirical Examination and Policy Mechanisms for Stimulating Additional Production." (2002). With Robert H. Baumann and Dmitry V. Mesyanzhinov. Louisiana Office of Mineral Resources. Total Project Funding: $72,000. Status: Completed.

45. *Principal Investigator*. "A Collaborative Investigation of Baseline and Scenario Information for Environmental Impact Statements." (2002). With Dmitry V. Mesyanzhinov and Williams O. Olatubi. U.S. Department of Interior, Minerals Management Service. Total Project Funding: $557,744. Status: Awarded, In Progress.

46. *Co-Principal Investigator*. "An Analysis of the Economic Impacts of Drilling and Production Activities on State Leases." (2002). With Robert H. Baumann, Allan G. Pulsipher, and Dmitry V. Mesyanzhinov. Louisiana Office of Mineral Resources. Total Project Funding: $8,000. Status: Completed.

47. *Principal Investigator*. "Cost Profiles and Cost Functions for Gulf of Mexico Oil and Gas Development Phases for Input Output Modeling." (1998). With Dmitry Mesyanzhinov and Allan G. Pulsipher. U.S. Department of Interior, Minerals Management Service. Total Project Funding: $244,956. Status: Completed.

48. *Principal Investigator*. "An Economic Impact Analysis of OCS Activities on Coastal Louisiana." (1998). With Dmitry Mesyanzhinov and David Hughes. U.S. Department of Interior, Minerals Management Service. Total Project Funding: $190,166. Status: Completed.

49. *Principal Investigator*. "Energy Conservation and Electric Restructuring in Louisiana." (1997). Louisiana Department of Natural Resources." Petroleum Violation Escrow Program Funds. Total Project Funding: $43,169. Status: Completed.

50. *Principal Investigator*. "The Industrial Supply of Electricity: Commercial Generation, Self-Generation, and Industry Restructuring." (1996). With Andrew Kleit. Louisiana Energy Enhancement Program, LSU Office of Research and Development. Total Project Funding: $19,948. Status: Completed.

51. *Co-Principal Investigator*. "Assessing the Environmental and Safety Risks of the Expanded Role of Independents in Oil and Gas E&P Operations on the U.S. Gulf of Mexico OCS." (1996). With Allan Pulsipher, Omowumi Iledare, Dmitry Mesyanzhinov, William Daniel, and Bob Baumann. U.S. Department of Interior, Minerals Management Service, Grant Number 95-0056. Total Project Funding: $109,361. Status: Completed.

ACADEMIC CONFERENCE PAPERS/PRESENTATIONS

1. "The changing nature of Gulf of Mexico energy infrastructure." (2017). Session 3B: New Directions in Social Science Research. 27th Gulf of Mexico Region Information Technology Meetings. U.S. Department of the Interior, Bureau of Ocean Energy Management, Environmental Studies Program. New Orleans, LA. August 24.

2. "Capacity utilization, efficiency trends, and economic risks for modern CHP installations." (2017). U.S. Department of Energy, 2017 Industrial Energy Technology Conference, New Orleans, LA June 21.

3. “Vulnerability assessment of the central Gulf of Mexico coast using a multi-dimensional approach.” (2016). With Siddhartha Narra. Eighth International Conference on Environmental Science and Technology. June 6-10, Houston, TX.

4. “The Impact of Infrastructure Cost Recovery Mechanisms on Pipeline Replacements and Leaks.” (2015). With Gregory Upton. Southern Economic Association Meeting 2015. New Orleans, Louisiana. November 23.

5. “The Impact of Infrastructure Cost Recovery Mechanisms on Pipeline Replacements and Leaks” (2015). With Gregory Upton. 38th IAEE International Conference, Antalya, Turkey. May 26.

6. “Modifying Renewables Policies to Sustain Positive Economic and Environmental Change” (2015). IEEE Annual Green Technologies (“Greentech”) Conference. April 17.

7. “The Gulf Coast Industrial Investment Renaissance and New CHP Development Opportunities.” (2014). Industrial Energy and Technology Conference, New Orleans, Louisiana. May 20.

8. “Estimating Critical Energy Infrastructure Value at Risk from Coastal Erosion” (2014). With Siddhartha Narra. American’s Estuaries: 7th Annual Summit on Coastal and Estuarine Habitat Restoration. Washington, D.C., November 3-6.

9. “Economies of Scale, Learning Curves, and Offshore Wind Development Costs” (2012). With Gregory Upton. Southern Economic Association Annual Conference, New Orleans, LA November 17.

10. “Analysis of Risk and Post-Hurricane Reaction.” (2009). 25th Annual Information Transfer Meeting. U.S. Department of the Interior, Minerals Management Service. January 7.

11. “Legacy Litigation, Regulation, and Other Determinants of Interstate Drilling Activity Differentials.” (2008). With Christopher Peters and Mark Kaiser. 28th Annual USAEE/IAEE North American Conference: Unveiling the Future of Future of Energy Frontiers. New Orleans, LA, December 3.

12. “Gulf Coast Energy Infrastructure Renaissance: Overview.” (2008). 28th Annual USAEE/IAEE North American Conference: Unveiling the Future of Future of Energy Frontiers. New Orleans, LA, December 3.

13. “Understanding the Impacts of Katrina and Rita on Energy Industry Infrastructure.” (2008). American Chemical Society National Meetings, New Orleans, Louisiana. April 7.

14. "Determining the Economic Value of Coastal Preservation and Restoration on Critical Energy Infrastructure." (2007). With Kristi A. R. Darby and Michelle Barnett. International Association for Energy Economics, Wellington, New Zealand, February 19.

15. “Regulatory Issues in Rate Design, Incentives, and Energy Efficiency.” (2007). 34th Annual Public Utilities Research Center Conference, University of Florida. Gainesville, FL. February 16.

16. “An Examination of LNG Development on the Gulf of Mexico.” (2007). With Kristi A.R. Darby. US Department of the Interior, Minerals Management Service. 24th Annual Information Technology Meeting. New Orleans, LA. January 9.

17. "OCS-Related Infrastructure on the GOM: Update and Summary of Impacts." (2007). U.S. Department of the Interior, Minerals Management Service. 24th Annual Information Technology Meeting. New Orleans, LA. January 10.

18. "The Economic Value of Coastal Preservation and Restoration on Critical Energy Infrastructure." (2006). With Michelle Barnett. Third National Conference on Coastal and Estuarine Habitat Restoration. Restore America's Estuaries. New Orleans, Louisiana, December 11.

19. "The Impact of Implementing a 20 Percent Renewable Portfolio Standard in New Jersey." (2006). With Seth E. Cureington. Mid-Continent Regional Science Association 37th Annual Conference, Purdue University, Lafayette, Indiana, June 9.

20. "The Impacts of Hurricane Katrina and Rita on Energy infrastructure Along the Gulf Coast." (2006). Environment Canada: 2006 Artic and Marine Oilspill Program. Vancouver, British Columbia, Canada.

21. "Hurricanes, Energy Markets, and Energy Infrastructure in the Gulf of Mexico: Experiences and Lessons Learned." (2006). With Kristi A.R. Darby and Seth E. Cureington. 29th Annual IAEE International Conference, Potsdam, Germany, June 9.

22. "An Examination of the Opportunities for Drilling Incentives on State Leases in Louisiana." (2005). With Kristi A.R. Darby. 28th Annual IAEE International Conference, Taipei, Taiwan (June).

23. "Fiscal Mechanisms for Stimulating Oil and Gas Production on Marginal Leases." (2004). With Jeffrey M. Burke. International Association of Energy Economics Annual Conference, Washington, D.C. (July).

24. "GIS and Applied Economic Analysis: The Case of Alaska Residential Natural Gas Demand." (2003). With Dmitry V. Mesyanzhinov. Presented at the Joint Meeting of the East Lakes and West Lakes Divisions of the Association of American Geographers in Kalamazoo, MI, October 16-18.

25. "Are There Any In-State Uses for Alaska Natural Gas?" (2002). With Dmitry V. Mesyanzhinov and William E. Nebesky. IAEE/USAEE 22nd Annual North American Conference: "Energy Markets in Turmoil: Making Sense of It All." Vancouver, British Columbia, Canada. October 7.

26. "The Economic Impact of State Oil and Gas Leases on Louisiana." (2002). With Dmitry V. Mesyanzhinov. 2002 National IMPLAN Users' Conference. New Orleans, Louisiana, September 4-6.

27. "Moving to the Front of the Lines: The Economic Impact of Independent Power Plant Development in Louisiana." (2002). With Dmitry V. Mesyanzhinov and Williams O. Olatubi. 2002 National IMPLAN Users' Conference. New Orleans, Louisiana, September 4-6.

28. "New Consistent Approach to Modeling Regional Economic Impacts of Offshore Oil and Gas Activities in the Gulf of Mexico." (2002). With Vicki Zatarain. 2002 National IMPLAN Users' Conference. New Orleans, Louisiana, September 4-6.

29. “Distributed Energy Resources, Energy Efficiency, and Electric Power Industry Restructuring.” (1999). American Society of Environmental Science Fourth Annual Conference. Baton Rouge, Louisiana. December.
30. “Estimating Efficiency Opportunities for Coal Fired Electric Power Generation: A DEA Approach.” (1999). With Williams O. Olatubi. Southern Economic Association Sixty-ninth Annual Conference. New Orleans, November.
31. "Applied Approaches to Modeling Regional Power Markets." (1999.) With Robert F. Cope. Southern Economic Association Sixty-ninth Annual Conference. New Orleans, November 1999.
32. “Parametric and Non-Parametric Approaches to Measuring Efficiency Potentials in Electric Power Generation.” (1999). With Williams O. Olatubi. International Atlantic Economic Society Annual Conference, Montreal, October.
33. “Asymmetric Choice and Customer Benefits: Lessons from the Natural Gas Industry.” (1999). With Rachelle F. Cope and Dmitry Mesyanzhinov. International Association of Energy Economics Annual Conference. Orlando, Florida. August.
34. “Modeling Regional Power Markets and Market Power.” (1999). With Robert F. Cope. Western Economic Association Annual Conference. San Diego, California. July.
35. “Economic Impact of Offshore Oil and Gas Activities on Coastal Louisiana” (1999). With Dmitry Mesyanzhinov. Annual Meeting of the Association of American Geographers. Honolulu, Hawaii. March.
36. “Empirical Issues in Electric Power Transmission and Distribution Cost Modeling.” (1998). With Robert F. Cope and Dmitry Mesyanzhinov. Southern Economic Association. Sixty-Eighth Annual Conference. Baltimore, Maryland. November.
37. “Modeling Electric Power Markets in a Restructured Environment.” (1998). With Robert F. Cope and Dan Rinks. International Association for Energy Economics Annual Conference. Albuquerque, New Mexico. October.
38. “Benchmarking Electric Utility Distribution Performance.” (1998) With Robert F. Cope and Dmitry Mesyanzhinov. Western Economic Association, Seventy-sixth Annual Conference. Lake Tahoe, Nevada. June.
39. “Power System Operations, Control, and Environmental Protection in a Restructured Electric Power Industry.” (1998). With Fred I. Denny. IEEE Large Engineering Systems Conference on Power Engineering. Nova Scotia, Canada. June.
40. “Benchmarking Electric Utility Transmission Performance.” (1997). With Robert F. Cope and Dmitry Mesyanzhinov. Southern Economic Association, Sixty-seventh Annual Conference. Atlanta, Georgia. November 21-24.
41. “A Non-Linear Programming Model to Estimate Stranded Generation Investments in a Deregulated Electric Utility Industry.” (1997). With Robert F. Cope and Dan Rinks. Institute for Operations Research and Management Science Annual Conference. Dallas Texas. October 26-29.

42. "New Paradigms for Power Engineering Education." (1997). With Fred I. Denny. International Association of Science and Technology for Development, High Technology in the Power Industry Conference. Orlando, Florida. October 27-30

43. "Cogeneration and Electric Power Industry Restructuring." (1997). With Andrew N. Kleit. Western Economic Association, Seventy-fifth Annual Conference. Seattle, Washington. July 9-13.

44. "The Unintended Consequences of the Public Utilities Regulatory Policies Act of 1978." (1997). National Policy History Conference on the Unintended Consequences of Policy Decisions. Bowling Green State University. Bowling Green, Ohio. June 5-7.

45. "Assessing Environmental and Safety Risks of the Expanding Role of Independents in E&P Operations on the Gulf of Mexico OCS." (1996). With Allan Pulsipher, Omowumi Iledare, Dmitry Mesyanzhinov, and Bob Baumann. U.S. Department of Interior, Minerals Management Service, 16th Annual Information Transfer Meeting. New Orleans, Louisiana.

46. "Empirical Modeling of the Risk of a Petroleum Spill During E&P Operations: A Case Study of the Gulf of Mexico OCS." (1996). With Omowumi Iledare, Allan Pulsipher, and Dmitry Mesyanzhinov. Southern Economic Association, Sixty-Sixth Annual Conference. Washington, D.C.

47. "Input Price Fluctuations, Total Factor Productivity, and Price Cap Regulation in the Telecommunications Industry" (1996). With Farhad Niami. Southern Economic Association, Sixty-Sixth Annual Conference. Washington, D.C.

48. "Recovery of Stranded Investments: Comparing the Electric Utility Industry to Other Recently Deregulated Industries" (1996). With Farhad Niami and Dmitry Mesyanzhinov. Southern Economic Association, Sixty-Sixth Annual Conference. Washington, D.C.

49. "Spatial Perspectives on the Forthcoming Deregulation of the U.S. Electric Utility Industry." (1996) With Dmitry Mesyanzhinov. Southwest Association of American Geographers Annual Meeting. Norman, Oklahoma.

50. "Comparing the Safety and Environmental Performance of Offshore Oil and Gas Operators." (1995). With Allan Pulsipher, Omowumi Iledare, Dmitry Mesyanzhinov, William Daniel, and Bob Baumann. U.S. Department of Interior, Minerals Management Service, 15th Annual Information Transfer Meeting. New Orleans, Louisiana.

51. "Empirical Determinants of Nuclear Power Plant Disallowances." (1995). Southern Economic Association, Sixty-Fifth Annual Conference. New Orleans, Louisiana.

52. "A Cross-Sectional Model of IntraLATA MTS Demand." (1995). Southern Economic Association, Sixty-Fifth Annual Conference. New Orleans, Louisiana.

ACADEMIC SEMINARS AND PRESENTATIONS

1. Panelist. "Fuel Security, Resource Adequacy & Value of Transmission." (2019). 6th Annual Electricity Dialogue at Northwestern University: Energy and Capacity: Transitions? Northwestern University Center of Law, Regulation, and Economic Growth.

2. “Air Emissions Regulation and Policy: The Recently Proposed Cross State Air Pollution Rule and the Implications for Louisiana Power Generation.” Lecture before School of the Coast & Environment. November 5, 2011.
3. “Energy Regulation: Overview of Power and Gas Regulation.” Lecture before School of the Coast & Environment, Course in Energy Policy and Law. October 5, 2009.
4. “Trends and Issues in Renewable Energy.” Presentation before the School of the Coast & Environment, Louisiana State University. Spring Guest Lecture Series. May 4, 2007.
5. “CES Research Projects and Status.” Presentation before the U.S. Department of the Interior, Minerals Management Service, Outer Continental Shelf Scientific Committee Meeting, New Orleans, LA May 22, 2007.
6. “Hurricane Impacts on Energy Production and Infrastructure.” Presentation Before the 53rd Mineral Law Institute, Louisiana State University. April 7, 2006.
7. “Trends and Issues in the Natural Gas Industry and the Development of LNG: Implications for Louisiana. (2004) 51st Mineral Law Institute, Louisiana State University, Baton Rouge, LA. April 2, 2004.
8. “Electric Restructuring and Conservation.” (2001). Presentation before the Department of Electrical Engineering, McNesse State University. Lake Charles, Louisiana. May 2, 2001.
9. “Electric Restructuring and the Environment.” (1998). Environment 98: Science, Law, and Public Policy. Tulane University. Tulane Environmental Law Clinic. March 7, New Orleans, Louisiana.
10. “Electric Restructuring and Nuclear Power.” (1997). Louisiana State University. Department of Nuclear Science. November 7, Baton Rouge, Louisiana.
11. “The Empirical Determinants of Co-generated Electricity: Implications for Electric Power Industry Restructuring.” (1997). With Andrew N. Kleit. Florida State University. Department of Economics: Applied Microeconomics Workshop Series. October 17, Tallahassee, Florida.

PROFESSIONAL AND CIVIC PRESENTATIONS

1. “Gulf Coast Energy Outlook 2024.” (2023). LSU Center for Energy Studies, Baton Rouge, LA, Fall 2023.
2. “Louisiana clean, green industry: reconciling industrial decarbonization, capital formation, and growth.” (2023). Louisiana State Bar Association, Public Utility Section. December 1, 2023.
3. “Expert witness training: considerations for preparation and effective execution during public utility regulatory hearings and proceedings.” (2023). On the Behalf of the National Association of State Utility Consumer Advocates, Accounting and Finance Subcommittee. September 21, 2023.

4. “Gulf cost energy outlook: traditional resources and the energy transition.” (2023). AAPL/Gulf Coast Land Institute Meetings. April 26, 2023.

5. “Ratepayer considerations in the promotion of clean energy.” (2023). Public Utility Law Section Roundtable Discussion. April 21, 2023.

6. “Gulf coast energy outlook: traditional resources and the energy transition.” (2023). Louisiana Engineering Society. April 19, 2023.

7. “Carbon capture & storage: three thoughts and considerations.” (2023). Gulf Coast Power Association. 9th Annual MISO/SPP Conference. March 9, 2023.

8. “Natural gas markets: prices; trends; and ratepayer impacts.” (2023). Maryland Energy Advocates Virtual Monthly Meeting. February 17, 2023.

9. “Hydrogen overview and its role in Louisiana decarbonization.” (2022). Louisiana Public Service Commission Monthly Business & Executive Meeting. November 17, 2022.

10. “High winter natural gas prices and ratepayer impacts.” (2022). National Association of State Utility Consumer Advocates (“NASUCA”) Annual Conference. November 14, 2022.

11. “Facing the future together: the Louisiana energy transition, industrial decarbonization, and capital formation trends.” (2022). Louisiana Chemical Association: Annual Meeting 2022. October 27, 2022.

12. “Louisiana and the energy transition: reconciling industrial decarbonization, capital formation, and growth.” (2022). Louisiana Air and Waste Management 2022 Annual Meeting. October 26, 2022.

13. “The Louisiana energy transition, industrial decarbonization, and industrial capital formation trends.” (2022). Postlethwaite & Netterville: 2022 Governmental Update. August 4, 2022.

14. “Identifying and mapping regulatory requirements for CCUS projects.” (2022). SECARB Offshore GOM Gulf Regulator Workshop. New Orleans LA. May 16, 2022.

15. “Louisiana industrial decarbonization opportunities.” (2022). Louisiana Chemical Association/Louisiana Chemical Industry Alliance Legislative Meeting. May 11, 2022. Baton Rouge, LA.

16. “Natural Gas outlook, 2022: supply, demand, and geopolitical considerations.” (2022). National Association of State Utility Consumer Advocates (“NASUCA”) Monthly Natural Gas Committee Webinar. March 30, 2022.

17. “Louisiana industrial decarbonization opportunities.” (2022). LSU Law School, Journal of Energy Law and Resources Symposium on Energy Transitions. February 4, 2022. Baton Rouge, LA.

18. Panelist. Grid Resiliency in the Era of Extreme Weather. Gulf Coast Power Association 8th Annual MISO/SPP Regional Meeting. February 9, 2022. New Orleans, LA.

19. Panelist. Natural Gas Industry Update. (2022). National Association of State Utility Consumer Advocates Annual Meeting. (virtual). November 8, 2021.

20. “Overview of Louisiana’s greenhouse gas emissions and trends.” (2021). Louisiana Energy Users Group (“LEUG”) Meeting. November 11, 2021.

21. “State of energy in Louisiana: a preview of the 2021 Gulf Coast Energy Outlook.” (2021). Financial Planning Association of Baton Rouge. November 10, 2021.

22. “Replacing natural gas and industrial decarbonization: utility and ratemaking issues.” (2021). Virtual Joint Annual Meeting: Virginia Committee for Fair Utility Rates, Old Dominion Committee for Fair Utility Rates, and Virginia Industrial Gas Users Group Workshop. September 8, 2021.

23. “Louisiana 2021 GHG Inventory: Update and summary of preliminary findings.” (2021). Presentation before the Climate Initiative Task Force. July 29, 2021.

24. “Opportunities for the development of a hydrogen economy in Louisiana.” (2021). Louisiana Energy Climate Solutions Workshop. June 15, 2021.

25. “Natural gas: Building gas system resilience. Overview of the 2021 polar vortex and its implications for gas resiliency.” (2021). National Association of State Utility Consumer Advocates (“NASUCA”). Virtual mid-year meeting. June 14, 2021.

26. “Status and briefing on the Louisiana greenhouse gas inventory and emissions analysis.” (2021). Scientific Advisory Group (“SAG”) Meeting, Governor’s Climate Initiative Task Force. March 29, 2021.

27. “Louisiana carbon capture: sinks; sources; and the role of transportation in industrial applications.” (2021). LSU Journal of Energy Law & Resources Symposium on Carbon Capture and Solutions. February 5, 2021.

28. “Natural gas outlook, 2021: production, demand, pandemic and policy.” (2021). National Association of State Utility Consumer Advocates (“NASUCA”) Monthly Natural Gas Committee Webinar. January 20, 2021.

29. “Consumer Perspectives on the Rate Design of the Future.” (2020). National Association of State Utility Consumer Advocates (“NASUCA”). Annual Conference, November 10.

30. “Evaluation of Louisiana’s Depleted Gas Reservoirs for Geological Carbon Sequestration.” (2020). Louisiana Mid-Continent Oil and Gas Association (“LMOGA”) Carbon Capture and Underground Storage (“CCUS”) Committee Meeting. August 25.

31. “The 2020 Gulf Coast Energy Outlook: COVID-19 update.” (2020). Baton Rouge Area Chamber of Commerce Business Webinar. COVID-19 and Global Supply Impacts on the Capital Region and Louisiana Economies. Baton Rouge, LA. June 3.

32. “Ratepayer benefits of reforming PURPA”. (2020). Harvard Electricity Policy Group Webinar. PURPA: A time to reform or reduce its role? March 26.

33. “Pipeline industry: economic trends and outlook”. (2020). Joint Industry Association Annual Meeting. Louisiana Mid-Continent Oil and Gas Association (“LMOGA”) and the Louisiana Oil and Gas Association (“LOGA”). Lake Charles, LA March 5.

34. “The outlook for natural gas: storm clouds ahead?” (2020). National Association of State Utility Consumer Advocates (“NASUCA”). Natural Gas Committee Webinar, February 26.

35. “The 2020 Gulf Coast Energy Outlook”. (2020). University of Louisiana Lafayette, Southern Unconventional Resources Center for Excellence. Lafayette, LA February 16.

36. “Opportunities for carbon capture, utilization, and storage in the Louisiana chemical corridor”. (2020). Air and Waste Management Association, Louisiana Section Luncheon. Gonzales, LA January 16.

37. Panelist. (2020). Baton Route Advocate, 2020 Economic Outlook Summit. Baton Rouge Advocate. January 8.

38. “2020 Louisiana business climate outlook: the view from the energy sector.” (2019). American Council of Engineering Companies Fall Conference. November 21, 2019. Baton Rouge, LA

39. “The urgency of PURPA reform in protecting ratepayers.” (2019). Americans for Tax Reform, Fall 2019 Coalition Leaders Summit, November 14, 2019. New Orleans, LA.

40. “Louisiana’s coast and the energy industry.” (2019). 2019 API Delta Chapter Joint Society Luncheon Meeting. November 12, 2019, New Orleans, LA.

41. “Reforming PURPA: implications for ratepayers.” (2019). Thomas Jefferson Institute for Public Policy, Annual Energy Summit, State Policy Network Annual Meeting. Colorado Springs, CO, October 28.

42. “Natural gas outlook: supply, demand and prices.” (2019). National Association of State Utility Consumer Advocates, Natural Gas Committee Monthly Meeting. July 30, 2019.

43. “The economic impacts and outlook for LNG development on the Gulf Coast.” (2019). 73rd Annual Meeting of the Southern Legislative Conference of the Council of State Governments. New Orleans, LA, July 14. (prepared presentation, hurricane cancellation)

44. “Natural gas outlook: supply, demand, and prices.” (2019). NASUCA Mid-Year Meeting. Portland, OR, June 20.

45. “Overview of Louisiana LNG issues and trends.” (2019). Berlin: LNG, Energy Security, and Diversity Reporting Tour, LSU Center for Energy Studies. Baton Rouge, LA, May 9.

46. “Overview of Louisiana energy issues and outlook.” (2019). Australian Media Visit, Greater New Orleans, Inc./Baton Rouge Area Foundation. Baton Rouge, LA, April 29.

47. “Gulf Coast Energy Outlook 2019: Regional trends and outlook.” (2019). Women’s Energy Network. Baton Rouge, LA, April 23.

48. “MISO Grid Vision 2033.” (2019). 2019 Spring Regulator and Policymaker Forum. New Orleans, LA, April 15-16.

49. “Ratepayer benefits of reforming PURPA.” (2019). LSU Center for Energy Studies Industry Advisory Council Meeting. March 27.

50. “Incentives, risk, and the changing nature of regulation.” (2019). NASUCA Water Committee monthly meeting/webinar. March 13.

51. “Gulf Coast Energy Outlook 2019: Production, trade and infrastructure trends.” (2019). 66th Annual Mineral Board Institute Meetings. Baton Rouge, LA, March 14.

52. "A golden age: energy outlook 2019." (2019). Engineering News Record Webinar. February 13.
53. Panelist. (2019). Baton Route Advocate, 2019 Economic Outlook Summit. Baton Rouge Advocate. January 8.
54. "MISO Grid Vision 2033." (2018). 2018 Winter Regulatory and Policymaker Forum. New Orleans, LA, December 11.
55. "Gulf Coast Energy Outlook 2019." (2018). LSU Center for Energy Studies, Baton Rouge, LA, Fall 2018.
56. "How LNG is transforming Louisiana's energy economy." (2018). Louisiana State Bar Association, Public Utility Section. Baton Rouge, LA, November 30.
57. "Overview of Louisiana LNG issues and trends." (2018). Kean Miller Law Firm: Energy and Environmental Practice Group. Baton Rouge, LA, November 28.
58. "Infrastructure and capacity: challenges for development." (2018). Society of Utility and Regulatory Financial Analysts (SURFA) Annual Meeting, New Orleans, LA, April 20.
59. "Louisiana industrial cogeneration trends." (2018). Annual Louisiana Solid Waste Association Conference, Lafayette, LA, March 16.
60. "Gulf Coast industrial development: overview of trends and issues." (2018). Gulf Coast Power Association Meetings, New Orleans, LA, February 8.
61. "Energy outlook – reflection on market trends and Louisiana implications." (2017). IberiaBank Corporation Bank Board of Directors Meeting, New Orleans, LA. November 15.
62. "Integrated carbon capture and storage in the Louisiana chemical corridor." (2017). Industry Associates Advisory Council Meeting, Baton Rouge, LA. November 7.
63. "The outlook for natural gas and energy development on the Gulf Coast." (2017). Louisiana Chemical Association, Annual Meeting, New Orleans, LA. October 26.
64. "Critical energy infrastructure: the big picture on resiliency research." (2017). National Academies of Science, Engineering, and Medicine. New Orleans, LA. September 18.
65. "The changing nature of Gulf of Mexico energy infrastructure." (2017). 27th Gulf of Mexico Region Information Technology Meetings, New Orleans, LA, August 24.
66. "Capacity utilization, efficiency trends, and economic risks for modern CHP installations." (2017). Industrial Energy Technology Conference, New Orleans, LA. June 21.
67. "Crude oil and natural gas outlook: Where are we and where are we going?" (2017). CCREDC Economic Trends Panel. Corpus Christi, TX, June 15.
68. "Navigating through the energy landscape." (2017). Baton Rouge Rotary Luncheon. Baton Rouge, LA, May 24.
69. "The 2017-2018 Louisiana energy outlook." (2017). Junior Achievement of Greater New Orleans, JA BizTown Speaker Series. New Orleans, LA, May 12.

70. "The Gulf Coast energy economy: trends and outlook." (2017). Society for Municipal Analysts. New Orleans, LA, April 21.

71. "Gulf coast energy outlook." (2017). E.J. Ourso College of Business, Dean's Advisory Council, Energy Committee Meeting. Baton Rouge, LA, March 31.

72. "Recent trends in energy: overview and impact for the banking community." (2017). Oil and Gas Industry Update, Louisiana Bankers Association. Baton Rouge, LA, March 24.

73. "How supply, demand and prices have influenced unconventional development." (2016). Energy Annual Meeting, CLEER-University Advisory Board Lecture. New Orleans, LA, September 17.

74. "The Basics of Natural Gas Production, Transportation, and Markets." (2016). Center for Energy Studies. Baton Rouge, LA, August 1.

75. "Gulf Coast industrial development: trends and outlook." (2016). Investor Relations Group Meeting, Edison Electric Institute. New Orleans, LA, June 23.

76. "The future of policy and regulation: Unlocking the Treasures of Utility Regulation." (2016). Annual Meeting, National Conference of Regulatory Attorneys. Tampa, FL, June 20.

77. "Utility mergers: where's the beef?". (2016). National Association of State Utility Consumer Advocates Mid-Year Meetings. New Orleans, LA, June 6.

78. "Overview of the Clean Power Plan and its application to Louisiana." (2016). Shell Oil Company Internal Meeting. April 12.

79. "Energy and economic development on the Gulf Coast: trends and emerging challenges." (2016). Gas Processors Association Meeting. New Orleans, LA, April 11.

80. "Unconventional Oil and Gas Drilling Trends and Issues." (2016). French Delegation Visit, LSU Center for Energy Studies. March 16.

81. "Gulf Coast Industrial Growth: Passing clouds or storms on the horizon?" (2016). Gulf Coast Power Association Meetings. New Orleans, LA, February 18.

82. "The Transition to Crisis: What do the recent changes in energy markets mean for Louisiana?" (2016). Louisiana Independent Study Group. February 2.

83. "Regulatory and Ratepayer Issues in the Analysis of Utility Natural Gas Reserves Purchases" (2016). National Association of State Utility Consumer Advocates Gas Consumer Monthly Meeting. January 25.

84. "Emerging Issues in Fuel Procurement: Opportunities & Challenges in Natural Gas Reserves Investment." (2015). National Association of State Utility Consumer Advocates Annual Meeting. Austin, Texas. November 9.

85. "Trends and Issues in Net Metering and Solar Generation." (2015). Louisiana Rural Electric Cooperative Meeting. November 5.

86. "Electric Power: Industry Overview, Organization, and Federal/State Distinctions." (2015). EUCI. October 16.

87. "Natural Gas 101: The Basics of Natural Gas Production, Transportation, and Markets."

(2015). Council of State Governments Special Meeting on Gas Markets. New Orleans, LA. October 14.

88. "Update and General Business Matters." (2015). CES Industry Associates Meeting. Baton Rouge, Louisiana. Fall 2015.

89. "The Impact of Infrastructure Cost Recovery Mechanisms on Pipeline Replacements and Leaks." (2015). 38th IAEE 2015 International Conference. Antalya, Turkey. May 26.

90. "Industry on the Move – What's Next?" (2015). Event Sponsored by Regional Bank and 1012 Industry Report. May 5.

91. "The State of the Energy Industry and Other Emerging Issues." (2015). Lex Mundi Energy & Natural Resources Practice Group Global Meeting. May 5.

92. "Energy, Louisiana, and LSU." (2015). LSU Science Café. Baton Rouge, Louisiana. April 28.

93. "Energy Market Changes and Impacts for Louisiana." (2015). Kinetica Partners Shippers Meeting, New Orleans, Louisiana. April 22.

94. "Incentives, Risk and the Changing Nature of Utility Regulation." (2015). NARUC Staff Subcommittee on Accounting and Finance Meetings, New Orleans, Louisiana. April 22.

95. "Modifying Renewables Policies to Sustain Positive and Economic Change." (2015). IEEE Annual Green Technologies ("Greentech Conference"). April 17.

96. "Louisiana's Changing Energy Environment." (2015). John P. Laborde Energy Law Center Advisory Board Spring Meeting, Baton Rouge, Louisiana. March 27.

97. "The Latest and the Long on Energy: Outlooks and Implications for Louisiana." (2015). Iberia Bank Advisory Board Meeting, Baton Rouge, Louisiana. February 23.

98. "A Survey of Recent Energy Market Changes and their Potential Implications for Louisiana." (2015). Vistage Group, New Orleans, Louisiana. February 4.

99. "Energy Prices and the Outlook for the Tuscaloosa Marine Shale." (2015). Baton Rouge Rotary Club, Baton Rouge, Louisiana. January 28.

100. "Trends in Energy & Energy-Related Economic Development." (2014). Miller and Thompson Presentation, Baton Rouge, Louisiana. December 30.

101. "Overview EPA's Proposed Rule Under Section 111(d) of the Clean Air Act: Impacts for Louisiana." (2014). Louisiana State Bar: Utility Section CLE Annual Meeting, Baton Rouge, Louisiana. November 7.

102. "Overview EPA's Proposed Clean Power Plan and Impacts for Louisiana." (2014). Clean Cities Coalition Meeting, Baton Rouge, Louisiana. November 5.

103. "Impacts on Louisiana from EPA's Proposed Clean Power Plan." (2014). Air & Waste Management Annual Environmental Conference (Louisiana Chapter), Baton Rouge, Louisiana. October 29, 2014.

104. "A Look at America's Growing Demand for Natural Gas." (2014). Louisiana Chemical Association Annual Meeting, New Orleans, Louisiana. October 23.

105. "Trends in Energy & Energy-Related Economic Development." (2014). 2014 Government Finance Officer Association Meetings, Baton Rouge, Louisiana. October 9.

106. "The Conventional Wisdom Associated with Unconventional Resource Development." (2014). National Association for Business Economics Annual Conference, Chicago, Illinois. September 28.

107. Unconventional Oil & Natural Gas: Overview of Resources, Economics & Policy Issues. (2014). Society of Environmental Journalists Annual Meeting. New Orleans, Louisiana. September 4.

108. "Natural Gas Leveraged Economic Development in the South." (2014). Southern Governors Association Meeting, Little Rock, Arkansas. August 16.

109. "The Past, Present and Future of CHP Development in Louisiana." (2014). Louisiana Public Service Commission CHP Workshop, Baton Rouge, Louisiana. June 25.

110. "Regional Natural Gas Demand Growth: Industrial and Power Generation Trends." (2014). Kinetica Partners Shippers Meeting, New Orleans, Louisiana. April 30.

111. "The Technical and Economic Potential for CHP in Louisiana and the Impact of the Industrial Investment Renaissance on New CHP Capacity Development." (2014). Electric Power 2014, New Orleans, Louisiana. April 1.

112. "Industry Investments and the Economic Development of Unconventional Development." (2014). Tuscaloosa Marine Shale Conference & Expo, Natchez, Mississippi. March 31.

113. Discussion Panelist. Energy Outlook 2035: The Global Energy Industry and Its Impact on Louisiana, (2014). Grow Louisiana Coalition, Baton Rouge, Louisiana. March 18.

114. "Natural Gas and the Polar Vortex: Has Recent Weather Led to a Structural Change in Natural Gas Markets?" (2014). National Association of State Utility Consumer Advocates Monthly Gas Committee Meeting. February 19.

115. "Some Unconventional Thoughts on Regional Unconventional Gas and Power Generation Requirements." (2014). Gulf Coast Power Association Special Briefing, New Orleans, Louisiana. February 6.

116. "Leveraging Energy for Industrial Development." (2013). 2013 Governor's Energy Summit, Jackson, Mississippi. December 5.

117. "Natural Gas Line Extension Policies: Ratepayer Issues and Considerations." (2013). National Association of State Utility Consumer Advocates Annual Meeting, Orlando, Florida. November 19.

118. "Replacement, Reliability & Resiliency: Infrastructure & Ratemaking Issues in the Power & Natural Gas Distribution Industries." (2013). Louisiana State Bar, Public Utility Section Meetings. November 15.

119. "Natural Gas Markets: Leveraging the Production Revolution into an Industrial Renaissance." (2013). International Technical Conference, Houston, TX. October 11.

120. "Natural Gas, Coal & Power Generation Issues and Trends." (2013). Southeast Labor and Management Public Affairs Committee Conference, Chattanooga, Tennessee.

September 27.

121. "Recent Trends in Pipeline Replacement Trackers." (2013). National Association of State Utility Consumer Advocates Monthly Gas Committee Meeting. September 19.

122. Discussion Panelist (2013). Think About Energy Summit, America's Natural Gas Alliance, Columbus Ohio. September 16-17.

123. "Future Test Years: Issues to Consider." (2013). National Regulatory Research Institute, Teleseminar on Future Test Years. August 28.

124. "Industrial Development Outlook for Louisiana." (2013). Louisiana Water Synergy Project Meetings, Jones Walker Law Firm, Baton Rouge, Louisiana. July 30.

125. "Natural Gas & Electric Power Coordination Issues and Challenges." (2013). Utilities State Government Organization Conference, Pointe Clear, Alabama. July 9.

126. "Natural Gas Market Issues & Trends." (2013). Western Conference of Public Service Commissioners, Santa Fe, New Mexico. June 3.

127. "Louisiana Unconventional Natural Gas and Industrial Redevelopment." (2013). Louisiana Chemical Association/Louisiana Chemical Industry Alliance Annual Legislative Conference, Baton Rouge, Louisiana. May 8.

128. "Infrastructure Cost Recovery Mechanism: Overview of Issues." (2013). Energy Bar Association Annual Meeting, Washington, D.C. May 1.

129. "GOM Offshore Oil and Gas." (2013). Energy Executive Roundtable, New Orleans, Louisiana. March 27.

130. "Louisiana Unconventional Natural Gas and Industrial Redevelopment." (2013). Risk Management Association Luncheon, March 21.

131. "Natural Gas Market Update and Emerging Issues." (2013). NASUCA Gas Committee Conference Call/Webinar, March 12.

132. "Unconventional Resources and Louisiana's Manufacturing Development Renaissance." (2013). Baton Rouge Press Club, De La Ronde Hall, Baton Rouge, LA, January 28.

133. "New Industrial Operations Leveraged by Unconventional Natural Gas." (2013) American Petroleum Institute-Louisiana Chapter. Lafayette, LA, Petroleum Club, January 14.

134. "What's Going on with Energy? How Unconventional Oil and Gas Development is Impacting Renewables, Efficiency, Power Markets, and All that Other Stuff." (2012). Atlanta Economics Club Monthly Meeting. Atlanta, GA. December 11.

135. "Trends, Issues, and Market Changes for Crude Oil and Natural Gas." (2012). East Iberville Community Advisory Panel Meeting. St. Gabriel, LA. September 26.

136. "Game Changers in Crude and Natural Gas Markets." (2012). Chevron Community Advisory Panel Meeting. Belle Chase, LA, September 17.

137. "The Outlook for Renewables in a Changing Power and Natural Gas Market." (2012). Louisiana Biofuels and Bioprocessing Summit. Baton Rouge, LA. September 11.

138. "The Changing Dynamics of Crude and Natural Gas Markets." (2012). Chalmette Refining Community Advisory Panel Meeting. Chalmette, LA, September 11.

139. "The Really Big Game Changer: Crude Oil Production from Shale Resources and the Tuscaloosa Marine Shale." (2012). Baton Rouge Chamber of Commerce Board Meeting. Baton Rouge, LA, June 27.

140. "The Impact of Changing Natural Gas Prices on Renewables and Energy Efficiency." (2012). NASUCA Gas Committee Conference Call/Webinar. 12 June 2012.

141. "Issues in Gas-Renewables Coordination: How Changes in Natural Gas Markets Potentially Impact Renewable Development" (2012). Energy Bar Association, Louisiana Chapter, Annual Meeting, New Orleans, LA. April 12, 2012.

142. "Issues in Natural Gas End-Uses: Are We Really Focusing on the Real Opportunities?" (2012). Energy Bar Association, Louisiana Chapter, Annual Meeting, New Orleans, LA. April 12, 2012.

143. "The Impact of Legacy Lawsuits on Conventional Oil and Gas Drilling in Louisiana." (2012). Louisiana Oil and Gas Association Annual Meeting, Lake Charles, LA. February 27, 2012.

144. "The Impact of Legacy Lawsuits on Conventional Oil and Gas Drilling in Louisiana." (2012) Louisiana Oil and Gas Association Annual Meeting. Lake Charles, Louisiana. February 27, 2012.

145. "Louisiana's Unconventional Plays: Economic Opportunities, Policy Challenges. Louisiana Mid-Continent Oil and Gas Association 2012 Annual Meeting. (2012) New Orleans, Louisiana. January 26, 2012.

146. "EPA's Recently Proposed Cross State Air Pollution Rule ("CSAPR") and Its Impacts on Louisiana." (2011). Bossier Chamber of Commerce. November 18, 2011.

147. "Facilitating the Growth of America's Natural Gas Advantage." (2011). BASF U.S. Shale Gas Workshop Management Meeting. Florham Park, New Jersey. November 1, 2011.

148. "CSAPR and EPA Regulations Impacting Louisiana Power Generation." (2011). Air and Waste Management Association (Louisiana Section) Fall Conference. Environmental Focus 2011: a Multi-Media Forum. Baton Rouge, LA. October 25, 2011.

149. "Natural Gas Trends and Impact on Industrial Development." (2011). Central Gulf Coast Industrial Alliance Conference. Arthur R. Outlaw Convention Center. Mobile, AL. September 22, 2011.

150. "Energy Market Changes and Policy Challenges." (2011). Southeast Manpower Tripartite Alliance ("SEMTA") Summer Conference. Nashville, TN September 2, 2011.

151. "EPA Regulations, Rates & Costs: Implications for U.S. Ratepayers." (2011). Workshop: "A Smarter Approach to Improving Our Environment." 38th Annual American Legislative Exchange Council ("ALEC") Meetings. New Orleans, LA. August 5, 2011.

152. Panelist/Moderator. Workshop: "Why Wait? Start Energy Independence Today." 38th Annual American Legislative Exchange Council ("ALEC") Meetings. New Orleans, LA.

August 4, 2011.

153. "Facilitating the Growth of America's Natural Gas Advantage." Texas Chemical Council, Board of Directors Summer Meeting. San Antonio, TX. July 28, 2011.

154. "Creating Ratepayer Benefits by Reconciling Recent Gas Supply Opportunities with Past Policy Initiatives." National Association of State Utility Consumer Advocates ("NASUCA"), Monthly Gas Committee Meeting. July 12, 2011.

155. "Energy Market Trends and Policies: Implications for Louisiana." (2011). Lakeshore Lion's Club Monthly Meeting. Baton Rouge, Louisiana. June 20, 2011.

156. "America's Natural Gas Advantage: Securing Benefits for Ratepayers Through Paradigm Shifts in Policy." Southeastern Association of Regulatory Commissioners ("SEARUC") Annual Meeting. Nashville, Tennessee. June 14, 2011.

157. "Learning Together: Building Utility and Clean Energy Industry Partnerships in the Southeast." (2011). American Solar Energy Society National Solar Conference. Raleigh Convention Center, Raleigh, North Carolina. May 20, 2011.

158. "Louisiana Energy Outlook and Trends." (2011). Executive Briefing. Counsul General of Canada. LSU Center for Energy Studies, Baton Rouge, Louisiana. May 24, 2011.

159. "Louisiana's Natural Gas Advantage: Can We Hold It? Grow It? Or Do We Need to be Worrying About Other Problems?" (2011). Louisiana Chemical Association Annual Legislative Conference, Baton Rouge, Louisiana, May 5, 2011.

160. "Energy Outlook and Trends: Implications for Louisiana. (2011). Executive Briefing, Legislative Staff, Congressman William Cassidy. LSU Center for Energy Studies, Baton Rouge, Louisiana. March 25, 2011.

161. "Regulatory Issues in Inflation Adjustment Mechanisms and Allowances." (2011). Gas Committee, National Association of State Utility Consumer Advocates ("NASUCA"). February 15, 2011.

162. "Regulatory Issues in Inflation Adjustment Mechanisms and Allowances." (2010). 2010 Annual Meeting, National Association of State Utility Consumer Advocates ("NASUCA"), Omni at CNN Center, Atlanta, Georgia, November 16, 2010.

163. "How Current and Proposed Energy Policy Impacts Consumers and Ratepayers." (2010). 122nd Annual Meeting, National Association of Regulatory Utility Commissioners ("NARUC"), Omni at CNN Center, Atlanta, Georgia, November 15, 2010.

164. "Energy Outlook: Trends and Policies." (2010). 2010 Tri-State Member Service Conference; Arkansas, Louisiana, and Mississippi Electric Cooperatives. L'Auberge du Lac Casino Resort, Lake Charles, Louisiana, October 14, 2010.

165. "Deepwater Moratorium and Louisiana Impacts." (2010). The Energy Council Annual Meeting. Gulf of Mexico Deepwater Horizon Accident, Response, and Policy. Beau Rivage Conference Center. Biloxi, Mississippi. September 25, 2010.

166. "Overview on Offshore Drilling and Production Activities in the Aftermath of Deepwater Horizon." (2010) Jones Walker Banking Symposium. The Oil Spill: What Will it Mean for

Banks in the Region? New Orleans, Louisiana. August 31, 2010.

167. "Long-Term Energy Sector Impacts from the Oil Spill." (2010). Second Annual Louisiana Oil & Gas Symposium. The BP Gulf Oil Spill: Long-Term Impacts and Strategies. Baton Rouge Geological Society. August 16, 2010.

168. "Overview and Issues Associated with the Deepwater Horizon Accident." (2010). Global Interdependence Meeting on Energy Issues. Baton Rouge, LA. August 12, 2010.

169. "Overview and Issues Associated with the Deepwater Horizon Accident." (2010). Regional Roundtable Webinar. National Association for Business Economics. August 10, 2010.

170. "Deepwater Moratorium: Overview of Impacts for Louisiana." Louisiana Association of Business and Industry Meeting. Baton Rouge, LA. June 25, 2010.

171. Moderator. Senior Executive Roundtable on Industrial Energy Efficiency. U.S. Department of Energy Conference on Industrial Efficiency. Office of Renewable Energy and Energy Efficiency. Royal Sonesta Hotel, New Orleans, LA. May 21, 2010.

172. "The Energy Outlook: Trends and Policies Impacting Southeastern Natural Gas Supply and Demand Growth." Second Annual Local Economic Analysis and Research Network ("LEARN") Conference. Federal Reserve Bank of Atlanta. March 29, 2010.

173. "Natural Gas Supply Issues: Gulf Coast Supply Trends and Implications for Louisiana." Energy Bar Association, New Orleans Chapter Meeting. Jones Walker Law Firm. January 28, 2010, New Orleans, LA.

174. "Potential Impacts of Federal Greenhouse Gas Legislation on Louisiana Industry." LCA Government Affairs Committee Meeting. November 10, 2009. Baton Rouge, LA

EXPERT WITNESS, LEGISLATIVE, AND PUBLIC TESTIMONY; EXPERT REPORTS, RECOMMENDATIONS, AND AFFIDAVITS

1. Expert Testimony. Docket No. DPU 23-81. (2023). Before the Commonwealth of

Massachusetts Department of Public Utilities. *Petition of Fitchburg Gas and Electric Light Company d/b/a Unitil (Gas Division), pursuant to G.L. c. 164, § 94 and 220 CMR 5.00, for Approval of a General Increase in Base Distribution Rates for Gas Service and a Performance-Based Ratemaking Plan.* On Behalf of the Massachusetts Office of the Attorney General, Office of Ratepayer Advocacy. Issues: alternative regulation performance-based ratemaking, cost of service, revenue distribution, rate design.

2. Expert Testimony. Docket No. DPU 23-80. (2023). Before the Commonwealth of Massachusetts Department of Public Utilities. *Petition of Fitchburg Gas and Electric Light Company d/b/a Unitil (Electric Division), pursuant to G.L. c. 164, § 94 and 220 CMR 5.00, for Approval of a General Increase in Base Distribution Rates for Electric Service and a Performance-Based Ratemaking Plan.* On Behalf of the Massachusetts Office of the Attorney General, Office of Ratepayer Advocacy. Issues: alternative regulation performance-based ratemaking, cost of service, revenue distribution, rate design.

3. Expert Testimony. Cause No. 45933 (2023). Before the Indiana Utility Regulatory Commission. *Petition of Indiana Michigan Power Company an Indiana Corporation, for authority to increase rates and charges for electric utility service through a phase in rate adjustment; and for approval of related relief including: (1) revised depreciation rates, including cost of removal less salvage, and updated depreciation expense; (2) accounting relief, including deferrals and amortization; (3) inclusion of capital investment; (4) rate adjustment mechanism proposals, including new grant projects rider and modified tax rider; (5) a voluntary residential customer powerpay program; (6) waiver or declination of jurisdiction with respect to certain rules to facilitate implementation of the powerpay program; (7) cost recovery for cook plant subsequent license renewal evaluation project; and (8) new schedules of rates, rules and regulations.* On Behalf of Indiana Office of Utility Consumer Counselor. Issues: cost of service, rate design, revenue distribution, service fees.

4. Expert Report. (2023). *Alternative regulation deficiencies and potential ratepayer harms*. On Behalf of the Office of the Consumer Advocate of Iowa. October 3, 2023.

5. Expert Testimony. Docket No. 2023.06.057. (2023). Before the Public Service Commission of the State of Montana. *In the Matter of Energy West Montana's Application for Approval of Gas Cost Hedging Plan for West Yellowstone.* On Behalf of the Montana Consumer Counsel. Issues: gas hedging program.

6. Legislative Testimony. (2023). Ratepayer harms from alternative regulation in Oklahoma. Appearing on the Behalf of the Petroleum Alliance of Oklahoma. October 23, 2023.

7. Expert Testimony. Cause No. 45911. (2023). Before the State of Indiana Utility Regulatory Commission. *Petition of Indianapolis Power & Light Company D/B/A AES Indiana ("AES Indiana") for authority to increase rates and charges for electric utility service, and for approval of related relief, including (1) revised depreciation rates, (2) accounting relief, including deferrals and amortizations, (3) inclusion of capital investments, (4) rate adjustment mechanism proposals, including new economic development rider, (5) remote disconnect/reconnect process and (6) new schedules of rates, rules and regulations for service*. On Behalf of Indiana Office of Utility Consumer Counselor. Direct and Cross-Answering. Issues: allocated cost of service, revenue distribution, rate design, trackers.

8. Expert Testimony. Docket No. 23-06007. (2023). Before the Public Utilities Commission of Nevada. *In the Matter of the Application by Nevada Power Company D/B/A NV Energy, filed pursuant to NRS 704.110(3) and NRS 704.110(4), addressing its annual revenue requirement for general rates charged to all classes of electric customers.* On Behalf of the Nevada Bureau of Consumer Protection. Issues: marginal cost of service study, embedded cost of service study, revenue distribution, rate design.

9. Expert Testimony. Docket No. UE-230172. (2023). Before the Washington Utilities and Transportation Commission. *Washington Utilities and Transportation Commission, Complainant v. Pacificorp dba Pacific Power & Light Company, Respondent.* On Behalf of the Washington State Office of the Attorney General Public Counsel Unit. Issues: rate design, revenue distribution, cost of service.

10. Expert Testimony. Case No. U-21389. (2023). Before the Michigan Public Service Commission. *In the Matter of the Application of Consumers Energy Company for Authority to Increase its Rates for the Generation and Distribution of Electricity and for other Relief.* On Behalf of the Michigan Department of the Attorney General. Issues: capital expenditure adjustments, overview of proposal.

11. Expert Report. Case No. 22-1094-WW-AIR. (2023). *Audit of the Application to Increase Rates of Aqua Ohio, Inc. For the Period July 1, 2022 through June 30, 2023.* Prepared for the Public Utilities Commission of Ohio. Issues: cost of service, billing determinants, revenue distribution, rate design.

12. Expert Report. Case No. 22-1096-ST-AIR. (2023). *Audit of the Application to Increase Rates of Aqua Ohio Wastewater, Inc. For the period July 1, 2022 through June 30, 2023.* Prepared for the Public Utilities Commission of Ohio. Issues: cost of service, billing determinants, revenue distribution, rate design.

13. Expert Report. *Analysis of the effectiveness and ratepayer impacts regarding the Natural Gas Rate Stabilization Act of 2005. (S.C. Code Ann. Section 58-5-410).* On Behalf of the South Carolina Department of Consumer Affairs. July 27, 2023.

14. Expert Testimony. Docket No. 2023-70-G. (2023). Before the Public Service Commission of South Carolina. *In the Matter of: Dominion Energy South Carolina, Inc's application for adjustments in its natural gas rate schedules and tariffs.* On Behalf of the South Carolina Department of Consumer Affairs. Issues: revenue credit, revenue distribution, rate design. Direct and Surrebuttal.

15. Expert Testimony. Docket No. E-01345A-22-0144. (2023). Before the Arizona Corporation Commission. *In the Matter of the Application of Arizona Public Service Company for a hearing to determine the fair value of the utility property of the company for ratemaking purposes, to fix a just and reasonable rate of return thereon, and to approve rate schedules designed to develop such return. On Behalf of the Utilities Division Arizona Corporation Commission.* Issues: cost of service, revenue distribution, rate design. Direct and Surrebuttal.

16. Expert Testimony. Docket No. 23-0068 (consol.) 23-0069. (2023). Before the Illinois Commerce Commission. *North Shore Gas Company, The Peoples Gas Light and Coke Company Proposed general increase in rates and revisions to service classifications,*

riders and terms and conditions of service. On Behalf of the People of the State of Illinois. Issues: integrity management, infrastructure metrics, natural gas policy, state gas policy.

17. Expert Testimony. Docket No. 23-067. (2023). Before the Illinois Commerce Commission. *Ameren Illinois Company Proposed general increase in gas delivery service rates.* On Behalf of the Illinois Attorney General. Issues: integrity management, infrastructure metrics, natural gas policy, state gas policy.

18. Expert Testimony. Docket No. 23-066. (2023). Before the Illinois Commerce Commission. *Northern Illinois Gas Company d/b/a Nicor Gas Company Proposed general increase in gas rates.* On Behalf of the People of the State of Illinois. Issues: integrity management, infrastructure metrics, natural gas policy, state gas policy.

19. Expert Testimony. Docket No. U-22-081. (2023). Before the Regulatory Commission of Alaska. *In the Matter of the Revenue Requirement Study Designated as TA334-4 Filed by Enstar Natural Gas Company, A Division of SEMCO Energy, Inc.* On Behalf of the Attorney General, Regulatory Affairs & Public Advocacy Section. Issues: cost of service, rate design, revenue distribution.

20. Expert Testimony. Docket No. U-22-078. (2023). Before the Regulatory Commission of Alaska. *In the Matter of the Revenue Requirement Study and Tariff Filing Designated as TA510-1 Filed by Alaska Electric Light & Power Company.* On Behalf of the Office of the Attorney General, Regulatory Affairs & Public Advocacy Section. On Behalf of the Mississippi Public Utilities Staff. Issues: financial analysis, rates and cost trends, economic impacts of proposal.

97. Expert Testimony. Case No. 2017-00179. (2017). Before the Public Service Commission, Commonwealth of Kentucky. *Electronic Application of Kentucky power Company For (1) A General Adjustment of Its Rates for Electric Service; (2) An Order Approving Its 2017 Environmental Compliance Plan; (3) An Order Approving Its Tariffs and Riders; (4) An Order Approving Accounting Practices to Establish a Regulatory Asset or Liability Related to the Big Sandy 1 Operation Rider; and (5) An Order Granting All Other Required Approvals and Relief.* On Behalf of the Office of the Kentucky Attorney General. Issues: rate design, revenue allocation, economic development.

98. Expert Testimony. Docket No. 17-010-FR. (2017). Before the Arkansas Public Service Commission. *In the Matter of the Formula Rate Plan Filing of CenterPoint Energy Resources Corp. D/B/A CenterPoint Energy Arkansas Gas Pursuant to APSC Docket No. 15-098-U.* On Behalf of the Arkansas Attorney General Leslie Rutledge. Issues: cost of service, rate design, alternative regulation, formula rate plan.

99. Expert Testimony. Formal Case No. 1142. (2017). Before the Public Service Commission of the District of Columbia. *In the Matter of the Merger of AltaGas Ltd. and WGL Holdings, Inc.* On Behalf of the Office of the People's Counsel. Issues: merger/acquisition policy, financial risk, ring-fencing, and reliability.

100. Expert Testimony. D.P.U. 17-05. (2017). Before the Massachusetts Department of Public Utilities. *Petition of NSTAR Electric Company and Western Massachusetts Electric Company each d/b/a Eversource Energy for Approval of an Increase in Base Distribution Rates for Electric Service Pursuant to G.L. c. 164, § 94 and 220 C.M.R. § 5.00*. On Behalf of the Massachusetts Office of the Attorney General Office of Ratepayer Advocacy. Issues: performance-based ratemaking, multi-factor productivity estimation.

101. Deposition and Testimony. (2017) Before the Nebraska Section 70, Article 13 Arbitration Panel. *Northeast Nebraska Public Power District, City of South Sioux City Nebraska; City of Wayne, Nebraska; City of Valentine, Nebraska; City of Beatrice, Nebraska; City of Scribner, Nebraska; Village of Walthill, Nebraska, vs. Nebraska Public Power District.* On the Behalf of Baird Holm LLP for the Plaintiffs. Issues: rate discounts; cost of service; utility regulation, economic harm.

102. Expert Testimony. Docket No. 16-052-U. (2017). Before the Arkansas Public Service Commission. *In the Matter of the Application of the Oklahoma Gas and Electric Company for Approval of a General Change in Rates, Charges and Tariffs.* On the Behalf of the Office of Arkansas Attorney General Leslie Rutledge. Issues: cost of service, rate design, alternative regulation, formula rate plan.

103. Expert Testimony. Docket No. 16-KCPE-593-ACQ. (2016). Before the Kansas Corporation Commission. *In the Matter of the Joint Application of Great Plains Energy Incorporated, Kansas City Power & Light Company, and Westar Energy, Inc. for Approval of the Acquisition of Westar, Inc. by Great Plains Energy Incorporated.* On the Behalf of the Kansas Electric Power Cooperative, Inc. Issues: merger/acquisition policy, financial risk, and ring-fencing.

104. Expert Testimony. Formal Case No. 1139. (2016). Before the Public Service Commission of the District of Columbia. *In the Matter of the Application of Potomac Electric Power Company for Authority to Increase Existing Retail Rates and Charges for Electric Distribution Service.* On the Behalf of the Office of the People's Counsel for the District of Columbia. Issues: cost of service, rate design, alternative regulation.

105. Expert Affidavit. Docket No. CP15-558-000 (2016). Before the United States of America Federal Energy Regulatory Commission. *PennEast Pipeline Company, LLC*. Affidavit and Reply Affidavit. On the Behalf of the New Jersey Division of Rate Counsel. Issues: pipeline capacity, peak day requirements.

106. Expert Testimony. Docket No. RPU-2016-0002. (2016). Before the Iowa Utilities Board. *In re: Iowa American Water Company application for revision of rates.* On behalf of the Office of Consumer Advocate. Issue: revenue stabilization mechanism, revenue decoupling.

107. Expert Testimony. Docket No. 15-015-U. (2016). Before the Arkansas Public Service Commission. *In the Matter of the Formula Rate Plan Filings of Entergy Arkansas, Inc., Pursuant to APSC Docket No. 15-015-U*. On behalf of the Office of the Arkansas Attorney General Leslie Rutledge. Issue: formula rate plan evaluation.

108. Expert Testimony. Docket Nos. 160021-EI, 160061-EI, 160062-EI, and 160088-EI. (2016). Before the Florida Public Service Commission. *In re: Petition for rate increase by Florida Power & Light Company (consolidated).* On behalf of the Citizens of the State of Florida. Issue: load forecasting.

109. Expert Testimony. Docket Nos. 160021-EI, 160061-EI, 160062-EI, and 160088-EI. (2016). Before the Florida Public Service Commission. *In re: Petition for rate increase by Florida Power & Light Company (consolidated).* On behalf of the Citizens of the State of Florida. Issue: off-system sales incentives.

110. Expert Testimony. Project No. 5-103. (2016). United States of America Federal Energy Regulatory Commission. *Confederated Salish and Kootenai Tribes Energy Keepers, Incorporated*. On behalf of the Flathead, Mission, and Jocko Valley Irrigation Districts and the Flathead Joint Board of Control of the Flathead, Mission, and Jocko Valley Irrigation Districts.

111. Expert Testimony. Docket No. 15-098-U. (2016). Before the Arkansas Public Service Commission. *In the Matter of the Application of CenterPoint Energy Resources Corp. d/b/a CenterPoint Energy Arkansas Gas for a General Change or Modification in its Rates, Charges and Tariffs.* On behalf of the Office of the Arkansas Attorney General. Issues: formula rate plan, cost of service and rate design.

112. Expert Testimony. BPU Docket No. GM15101196. (2016). *In the Matter of the Merger of Southern Company and AGL Resources, Inc*. On behalf of the New Jersey Division of Rate Counsel. Issues: merger standards of review, customer dividend contributions, synergy savings and costs to achieve, ratemaking treatment of merger-related costs.

113. Expert Testimony. Docket No. 15-078-U. (2015). Before the Arkansas Public Service Commission. *In the Matter of the Joint Application of SourceGas Inc., SourceGas LLC, SourceGas Holdings LLC and Black Hills Utility Holdings, Inc. for all Necessary Authorizations and Approvals for Black Hills Utility Holdings, Inc. to Acquire SourceGas Holdings LLC.* On behalf of the Office of the Arkansas Attorney General. Issues: public policy and regulatory policy associated with the acquisition.

114. Expert Testimony. Docket No. 15-031-U. (2015). Before the Arkansas Public Service Commission. *In the Matter of the Application of SourceGas Arkansas Inc. for an Order Approving the Acquisition of Certain Storage Facilities and the Recovery of Investments and Expenses Associated Therewith.* On behalf of the Office of the Arkansas Attorney General. Issues: cost-benefit analysis, transmission cost analysis, and a due diligence analysis.

115. Expert Testimony. Docket No. 15-015-U. (2015). Before the Arkansas Public Service Commission. *In the Matter of the Application of Entergy Arkansas, Inc. for Approval of Changes in Rates for Retail Electric Service.* On behalf of the Office of the Arkansas Attorney General. Issues: economic development riders and production plant cost allocation.

116. Expert Testimony. Docket No. 7970. (2015). Before the Vermont Public Service Board. *Petition of Vermont Gas Systems, Inc., for a certificate of public good pursuant to 30 V.S.A.§ 248, authorizing the construction of the "Addison Natural Gas Project" consisting of approximately 43 miles of new natural gas transmission pipeline in Chittenden and Addison Counties, approximately 5 miles of new distribution mainlines in Addison County, together with three new gate stations in Williston, New Haven, and Middlebury, Vermont*. On behalf of AARP-Vermont. Issues: net economic benefits of proposed natural gas transmission project.

117. Expert Testimony. File No. ER-2014-0370 (2015). Before the Public Service Commission of the State of Missouri. *In the Matter of Kansas City Power & Light Company for Authority Implement A General Rate Increase for Electric Service*. On behalf of the Missouri Office of the People's Counsel. Issues: customer charges, rate design, revenue distribution, class cost of service, and policy and ratemaking considerations in connection with electric vehicle charging stations.

118. Expert Testimony. File No. ER-2014-0351 (2015). Before the Public Service Commission of the State of Missouri. *In the Matter of The Empire District Electric Company for Authority To File Tariffs Increasing Rates for Electric Service Provided to Customers In the Company's Missouri Service Area*. On behalf of the Missouri Office of the People's Counsel. Issues: customer charges, rate design, revenue distribution, and class cost of service.

119. Expert Testimony. D.P.U. 14-130 (2015). Before the Massachusetts Department of Public Utilities. *Petition of Fitchburg Gas and Electric Light Company d/b/a Unitil for approval by the Department of Public Utilities of the Company's 2015 Gas System Enhancement Program Plan, pursuant to G.L. c. 164, § 145, and for rates effective May 1, 2015.* On behalf of the Attorney General's Office. Issues: ratepayer protections, cost allocations, rate design, performance metrics.

120. Expert Testimony. D.P.U. 14-131 (2015). Before the Massachusetts Department of Public Utilities. *Petition of The Berkshire Gas Company for approval by the Department of Public Utilities of the Company's Gas System Enhancement Program Plan for 2015, pursuant to G.L. c. 164, § 145, and for rates effective May 1, 2015*. On behalf of the Attorney General's Office. Issues: ratepayer protections, cost allocations, rate design, performance metrics.

121. Expert Testimony. D.P.U. 14-132 (2015). Before the Massachusetts Department of Public Utilities. *Petition of Boston Gas Company and Colonial Gas Company d/b/a National Grid for approval by the Department of Public Utilities of the Companies' Gas System Enhancement Program for 2015, pursuant to G.L. c. 164, § 145, and for rates effective May 1, 2015*. On behalf of the Attorney General's Office. Issues: ratepayer protections, cost allocations, rate design, performance metrics.

122. Expert Testimony. D.P.U. 14-133 (2015). Before the Massachusetts Department of Public Utilities. *Petition of Liberty Utilities for approval by the Department of Public Utilities of the Company's Gas System Enhancement Program Plan for 2015, pursuant to G.L. c. 164, § 145, and for rates effective May 1, 2015*. On behalf of the Attorney General's Office. Issues: ratepayer protections, cost allocations, rate design, performance metrics.

123. Expert Testimony. D.P.U. 14-134 (2015). Before the Massachusetts Department of Public Utilities. *Petition of Bay State Gas Company d/b/a Columbia Gas of Massachusetts for approval by the Department of Public Utilities of the Company's Gas System Enhancement Program Plan for 2015, pursuant to G.L. c. 164, § 145, and for rates to be effective May 1, 2015*. On behalf of the Attorney General's Office. Issues: ratepayer protections, cost allocations, rate design, performance metrics.

124. Expert Testimony. D.P.U. 14-135 (2015). Before the Massachusetts Department of Public Utilities. *Petition of NSTAR Gas Company for approval by the Department of Public Utilities of the Company's Gas System Enhancement Program Plan for 2015, pursuant to G.L. c. 164, § 145, and for rates to be effective May 1, 2015*. On behalf of the Attorney General's Office. Issues: ratepayer protections, cost allocations, rate design, performance metrics.

125. Expert Report. Docket No. X-33192 (2015). Before the Louisiana Public Service Commission. *Examination of the Comprehensive Costs and Benefits of Net Metering in Louisiana.* On behalf of the Louisiana Public Service Commission. Issues: cost-benefit, cost of service, rate impact.

126. Expert Testimony. F.C. 1119 (2014). Before the District of Columbia Public Service Commission. *In the Matter of the Merger of Exelon Corporation, Pepco Holdings, Inc., Potomac Electric Power Company, Exelon Energy Delivery Company, LLC, and new Special Purpose Entity, LLC*. On behalf of the Office of the People's Counsel. Issues: economic impact analysis, reliability, consumer investment fund, regulatory oversight, impacts to competitive electricity markets.

127. Expert Report. Civil Action 1:08-cv-0046 (2014). Before the U.S. District Court for the Southern District of Ohio. *Anthony Williams, et al., v. Duke Energy International, Inc., et al.* On behalf of Markovits, Stock & DeMarco, Attorneys & Counselors at Law. Issues: public utility regulation, electric power markets, economic harm.

128. Expert Testimony. D.P.U. 14-64 (2014). Before the Massachusetts Department of Public Utilities. *NSTAR Gas Company/HOPCO Gas Services Agreement. On behalf of the Office of the Public Advocate*. Issues: certain ratemaking features associated with the proposed Gas Service Agreement.

129. Expert Testimony. Docket Nos. 14-0224 and 14-0225 (2014). Before the Illinois Commerce Commission. *In the Matter of the Peoples Gas Light and Coke Company and North Shore Gas Company Proposed General Increase in Rates for Gas Service (consolidated)*. On behalf of the People of the State of Illinois. Issues: test year expenses, cost benchmarking analysis, pipeline replacement, and leak rate comparisons.

130. Expert Testimony. Docket 8191 (2014). Before the Vermont Public Service Board. *In Re: Petition of Green Mountain Power Corporation for Approval of a Successor Alternative*

Regulation Plan. On the behalf of AARP-Vermont. Issues: Alternative Regulation.

131. Expert Testimony. Docket No. 2013-00168 (2014). Before the Maine Public Utilities Commission. *In the Matter of the Request for Approval of an Alternative Rate Plan (ARP 2014) Pertaining to Central Maine Power Company*. On behalf of the Office of the Public Advocate. Issues: class cost of service study, marginal cost of service study, revenue distribution and rate design.

132. Expert Testimony. D.P.U. 13-90 (2013). Before the Massachusetts Department of Public Utilities. *Petition of Fitchburg Gas and Electric Light Company (Electric Division) d/b/a Unitil to the Department of Public Utilities for approval of the rates and charges and increase in base distribution rates for electric service.* On behalf of the Office of the Ratepayer Advocate. Issues: capital cost adjustment mechanism and performance-based regulation.

133. Expert Testimony. BPU Docket Nos. EO13020155 and GO13020156. (2013). Before the State of New Jersey Board of Public Utilities. *I/M/O The Petition of Public Service Electric & Gas Company for the Approval of the Energy Strong Program.* On behalf of the Division of Rate Counsel. Issues: economic impact, infrastructure replacement program rider, pipeline replacement, leak rate comparisons and cost benefit analysis.

134. Expert Testimony. D.P.U. 13-75 (2013). Before the Massachusetts Department of Public Utilities. *Investigation by the Department of Public Utilities on its Own Motion as to the Propriety of the Rates and Charges by Bay State Gas Company d/b/a Columbia Gas of Massachusetts set forth in Tariffs M.D.P.U. Nos. 140 through 173, and Approval of an Increase in Base Distribution Rates for Gas Service Pursuant to G.L. c. 164, § 94 and 220 C.M.R. § 5.00 et seq., filed with the Department on April 16, 2013, to be effective May 1, 2013*. On the Behalf of the Office of the Attorney General, Office of Ratepayer Advocacy. Issues: Target infrastructure replacement program rider, pipeline replacement, and leak rate comparisons; environmental benefits analysis; O&M offset; and cost benchmarking analysis.

135. Expert Testimony. Docket No. 13-115 (2013). Before the Delaware Public Service Commission. *In the Matter of the Application of Delmarva Power & Light Company FOR an Increase in Electric Base Rates and Miscellaneous Tariff Changes* (Filed March 22, 2013). On the Behalf of Division of the Public Advocate. Issues: pro forma infrastructure proposal, class cost of service study, revenue distribution, and rate design.

136. Expert Testimony. Formal Case No. 1103 (2013). Before the Public Service Commission of the District of Columbia. *In the Matter of the Application of the Potomac Electric Power Company for Authority to Increase Existing Retail Rates and Charges for Electric Distribution Service*. On the Behalf of the Office of the People's Counsel of the District of Columbia. Issues: Pro forma adjustment for reliability investments.

137. Expert Testimony. Case No. 9326 (2013). Before the Public Service Commission of Maryland. *In the Matter of the Application of Baltimore Gas and Electric Company for Adjustments to its Electric and Gas Base Rates*. On the Behalf of the Maryland Office of the People's Counsel. Issues: Electric Reliability Investment ("ERI") initiatives, pro forma gas infrastructure proposal, tracker mechanisms, class cost of service study, revenue

distribution, and rate design

138. Rulemaking Testimony. (2013). Before the Louisiana Tax Commission. Examination of Louisiana Assessors' Association Well Diameter Analysis, economic development policies regarding midstream assets and industrial development.

139. Expert Testimony. Case No. 9317 (2013). Before the Public Service Commission of Maryland. *In the Matter of the Application of Delmarva Power & Light Company for Adjustments to its Retail Rates for the Distribution of Electric Energy*. Direct, and Surrebuttal. On the Behalf of the Maryland Office of the People's Counsel. Issues: Grid Resiliency Charge, tracker mechanisms, pipeline replacement, class cost of service study, revenue distribution, and rate design.

140. Expert Testimony. Case No. 9311 (2013). Before the Public Service Commission of Maryland. *In the Matter of the Application of Potomac Electric Power Company for an Increase in its Retail Rates for the Distribution of Electric Energy*. Direct, and Surrebuttal. On the Behalf of the Maryland Office of the People's Counsel. Issues: Grid Resiliency Charge, tracker mechanisms, pipeline replacement, class cost of service study, revenue distribution, and rate design.

141. Expert Testimony. Docket No. 12AL-1268G (2013). Before the Public Utilities Commission of the State of Colorado. *In the Matter of the Tariff Sheets Filed by Public Service Company of Colorado with Advice No. 830 – Gas. Answer*. On the Behalf of the Colorado Office of Consumer Counsel. Issues: Pipeline System Integrity Adjustment, tracker mechanisms, pipeline replacement and leak rate comparisons.

142. Expert Testimony. BPU Docket No. EO12080721 (2013). Before the New Jersey Board of Public Utilities. *In the Matter of the Public Service Electric & Gas Company for Approval of an Extension of Solar Generation Program*. On the Behalf of the New Jersey Division of Rate Counsel. Direct, Rebuttal, Surrebuttal. Issues: solar energy market design, solar energy market conditions, solar energy program design and net economic benefits.

143. Expert Testimony. BPU Docket No. EO12080726 (2013). Before the New Jersey Board of Public Utilities. *In the Matter of the Petition of Public Service Electric & Gas Company for Approval of a Solar Loan III Program.* On the Behalf of the New Jersey Division of Rate Counsel. Direct, Rebuttal and Surrebuttal. Issues: solar energy market design, solar energy market conditions, solar energy program design.

144. Expert Testimony. BPU Docket No. EO11050314V. (2012). Before the New Jersey Board of Public Utilities. *In the Matter of the Petition of Fishermen's Atlantic City Windfarm, LLC for the Approval of the State Waters Project and Authorizing Offshore Wind Renewable Energy Certificates*. On the Behalf of the New Jersey Division of Rate Counsel. December 17, 2012. Issues: approval of offshore wind project and ratepayer financial support for the proposed project.

145. Expert Testimony. D.P.U. 12-25. (2012). Before the Massachusetts Department of Public Utilities. *In the Matter of Bay State Gas Company d/b/a/ Columbia Gas Company of Massachusetts Request for Increase in Rates*. On the Behalf of the Office of the Attorney General, Office of Ratepayer Advocacy. Issues: Target infrastructure replacement program rider, pipeline replacement and leak rate comparisons.

146. Expert Testimony. Docket Nos. UE-120436, et.al. (consolidated). (2012). Before the Washington Utilities and Transportation Commission. *Washington Utilities and Transportation Commission v. Avista Corporation D/B/A Avista Utilities*. On the Behalf of the Washington Attorney General, Office of the Public Counsel. Issues: Revenue Decoupling, lost revenues, tracker mechanisms, attrition adjustments.

147. Expert Testimony. Case No. 9286. (2012) Before the Public Service Commission of Maryland. *In Re: Potomac Electric Power Company ("Pepco") General Rate Case*. On the Behalf of the Maryland Office of the People's Counsel. Issues: Capital tracker mechanisms/reliability investment mechanisms, reliability issues, regulatory lag, class cost of service, revenue distribution, rate design.

148. Expert Testimony. Case No 9285. (2012) Before the Public Service Commission of Maryland. *In Re: the Delmarva Power and Light Company General Rate Case*. On the Behalf of the Maryland Office of the People's Counsel. Issues: Capital tracker mechanisms/reliability investment mechanisms, reliability issues, regulatory lag, class cost of service, revenue distribution, rate design.

149. Expert Testimony. Docket Nos. UE-110876 and UG-110877 (consolidated). (2012). Before the Washington Utilities and Transportation Commission. *Washington Utilities and Transportation Commission v. Avista Corporation D/B/A Avista Utilities*. On the Behalf of the Washington Attorney General, Office of the Public Counsel. Issues: Revenue Decoupling, lost revenues, tracker mechanisms.

150. Expert Testimony. BPU Docket No. EO11050314V. (2012). Before the New Jersey Board of Public Utilities. *In the Matter of the Petition of Fishermen's Atlantic City Windfarm, LLC for the Approval of the State Waters Project and Authorizing Offshore Wind Renewable Energy Certificates*. On the Behalf of the New Jersey Division of Rate Counsel. February 3, 2012. Issues: approval of offshore wind project and ratepayer financial support for the proposed project.

151. Expert Testimony. Docket No. NG 0067. (2012). Before the Public Service Commission of Nebraska. *In the Matter of the Application of SourceGas Distribution, LLC Approval of a General Rate Increase*. On the Behalf of the Public Advocate. January 31, 2012. Issues: Revenue Decoupling, Customer Adjustments, Weather Normalization Adjustments, Class Cost of Service Study, Rate Design.

152. Expert Testimony. Docket No. G-04204A-11-0158. (2011). Before the Arizona Corporation Commission. On the Behalf of the Arizona Corporation Commission Staff. *In the Matter of the Application of UNS Gas, Inc. for the Establishment of Just and Reasonable Rates and Charges Designed to Realize a Reasonable Rate of Return on the Fair Value of Its Arizona Properties*. Issues: Revenue Decoupling; Class Cost of Service Modeling; Revenue Distribution; Rate Design.

153. Expert Testimony. Formal Case Number 1087. (2011). Before the Public Service Commission of the District of Columbia. On the Behalf of the Office of the People's Counsel of the District of Columbia. *In the Matter of the Application of Potomac Electric Power Company for Authority to Increase Existing Retail Rates and Charges for Electric Distribution Service*. Issues: Regulatory lag, ratemaking principles, reliability-related

capital expenditure tracker proposals.

154. Expert Affidavit. Case No. 11-1364. (2011). *The State of Louisiana, the Louisiana Department of Environmental Quality, and the Louisiana Public Service Commission v. United States Environmental Protection Agency and Lisa P. Jackson.* Before the United States Court of Appeals for the District of Columbia Circuit. On the behalf of the State of Louisiana, the Louisiana Department of Environmental Quality, and the Louisiana Public Service Commission. Issues: Impacts of environmental costs on electric utilities, compliance requirements, investment cost of mitigation equipment, multi-area dispatch modeling and plant retirements.

155. Expert Affidavit. Docket No. EPA-HQ-OAR-2009-0491. (2011). Before the U.S. Environmental Protection Agency. *Federal Implementation Plans: Interstate Transport of Fine Particulate Matter and Ozone and Correction of SIP Approvals*. On the Behalf of the Louisiana Public Service Commission. Issues: Impacts of environmental costs on electric utilities, compliance requirements, investment cost of mitigation equipment, multi-area dispatch modeling and plant retirements.

156. Expert Testimony. Case No. 9296. (2011). Before the Maryland Public Service Commission. *On the Behalf of the Maryland Office of People's Counsel. In the Matter of the Application of Washington Gas Light Company for Authority to Increase Existing Rates and Charges and Revise its Terms and Conditions for Gas Service*. Issues: Infrastructure Cost Recovery Rider; Class Cost of Service Modeling; Revenue Distribution; Rate Design.

157. Expert Testimony. Docket No. G-01551A-10-0458. (2011). Before the Arizona Corporation Commission. On the Behalf of the Arizona Corporation Commission Staff. *In the Matter of the Application of Southwest Gas Corporation for the Establishment of Just and Reasonable Rates and Charges Designed to Realize A Reasonable Rate of Return on the Fair Value of its Properties throughout Arizona*. Issues: Revenue Decoupling; Class Cost of Service Modeling; Revenue Distribution; Rate Design.

158. Expert Testimony. Docket No. 11-0280 and 11-0281. (2011). Before the Illinois Commerce Commission. On the Behalf of the Illinois Attorney General, the Citizens Utility Board, and the City of Chicago, Illinois. *In re: Peoples Gas Light and Coke Company and North Shore Natural Gas Company*. Issues: Revenue Decoupling and Rate Design. (Direct and Rebuttal)

159. Expert Testimony. D.P.U. 11-01. (2011). Before the Massachusetts Department of Public Utilities. On the Behalf of the Office of the Attorney General, Office of Ratepayer Advocacy. *Petition of the Fitchburg Electric and Gas Company (Electric Division) for Approval of A General Increase in Electric Distribution Rates and Approval of a Revenue Decoupling Mechanism*. Issues: Capital Cost Rider, Revenue Decoupling.

160. Expert Testimony. D.P.U. 11-02. (2011). Before the Massachusetts Department of Public Utilities. On the Behalf of the Office of the Attorney General, Office of Ratepayer Advocacy. *Petition of the Fitchburg Electric and Gas Company (Gas Division) for Approval of A General Increase in Electric Distribution Rates and Approval of a Revenue Decoupling Mechanism*. Issues: Pipeline Replacement Rider, Revenue Decoupling.

161. Expert Affidavit. Docket No. EL-11-13 (2011). Before the Federal Energy Regulatory

Commission. Petition for Preliminary Ruling, Atlantic Grid Operations. On the Behalf of the New Jersey Division of Rate Counsel. Issues: Offshore wind generation development, offshore wind transmission development, ratemaking treatment of development costs, transmission development incentives.

162. Expert Opinion. Case No. CI06-195. (2011). Before the District Court of Jefferson County, Nebraska. On the Behalf of the City of Fairbury, Nebraska and Michael Beachler. In re: Endicott Clay Products Co. vs. City of Fairbury, Nebraska and Michael Beachler. Issues: rate design and ratemaking, time of use and time differentiated rate structures, empirical analysis of demand and usage trends for tariff eligibility requirements.

166. Expert Testimony. B.P.U Docket No. GR10030225. (2010). Before the New Jersey Board of Public Utilities. In the Matter of the Petition of New Jersey Natural Gas Company for Approval of Regional Greenhouse Gas Initiative Programs and Associated Cost Recovery Mechanisms Pursuant to N.J.S.A. 48:3-98.1. On the Behalf of the Department of the Public Advocate, Division of Rate Counsel. Issues: solar energy proposals, solar securitization issues, solar energy policy issues.

167. Expert Testimony. D.P.U. 10-55. (2010). Before the Massachusetts Department of Public Utilities. Investigation Into the Propriety of Proposed Tariff Changes for Boston Gas Company, Essex Gas Company, and Colonial Gas Company. (d./b./a. National Grid). On the Behalf of the Office of the Attorney General, Office of Ratepayer Advocacy. Issues: Revenue decoupling; pipeline-replacement rider; performance-based regulation; partial productivity factor estimates, inflation adjustment mechanisms; and rate design.

168. Expert Testimony. Cause No.43839. (2010). Before the Indiana Utility Regulatory Commission. In the Matter of Southern Indiana Gas and Electric Company d/b/a/ Vectren Energy Delivery of Indiana, Inc. (Vectren South-Electric). On the behalf of the Indiana Office of Utility Consumer Counselor (OUCC). Issues: revenue decoupling, variable production cost riders, gains on off-system sales, transmission cost riders.

169. Congressional Testimony. Before the United States Congress. (2010). U.S. House of

Representatives, Committee on Natural Resources. Hearing on the Consolidated Land, Energy, and Aquatic Resources Act. June 30, 2010.

170. Expert Testimony. Before the City Counsel of El Paso, Texas; Public Utility Regulatory Board. (2010). On the Behalf of the City of El Paso. In Re: Rate Application of Texas Gas Services, Inc. Issues: class cost of service study (minimum system and zero intercept analysis), rate design proposals, weather normalization adjustment, and its cost of service adjustment clause, conservation adjustment clause proposals, and other cost tracker policy issues.

171. Expert Testimony. Docket 09-00183. (2010). Before the Tennessee Regulatory Authority. In the Matter of the Petition of Chattanooga Gas Company for a General Rate Increase, Implementation of the EnergySMART Conservation Programs, and Implementation of a Revenue Decoupling Mechanism. On the Behalf of Tennessee Attorney General, Consumer Advocate & Protection Division. Issues: revenue decoupling and energy efficiency program review and cost effectiveness analysis.

172. Expert Testimony and Exhibits. Docket No. 10-240. (2010). Before the Louisiana Office of Conservation. In Re: Cadeville Gas Storage, LLC. On the Behalf of Cardinal Gas Storage, LLC. Issues: alternative uses and relative economic benefits of conversion of depleted hydrocarbon reservoir for natural gas storage purposes.

173. Expert Testimony. Docket No. 09505-EI. (2010). Before the Florida Public Service Commission. In Re: Review of Replacement Fuel Costs Associated with the February 26, 2008 outage on Florida Power & Light's Electrical System. On the Behalf of the Florida Office of Public Counsel for the Citizens of the State of Florida. Issues: Replacement costs for power outage, regulatory policy/generation development incentives, renewable and energy efficiency incentives.

174. Expert Report, Recommendation, and Proposed Rule: Docket Number R-29380-A, ex parte, (2009). Before the Louisiana Public Service Commission. In re: Environmental Adjustment Clause and Environmental Certification for Electric Power Generation Resources. On the behalf of the Louisiana Public Service Commission Staff. Report and Recommendation. Issues: environmental regulation and cost recovery; allowance allocations and air credit markets cost recovery treatment; other generation planning issues.

175. Expert Testimony. Docket 09-00104. (2009). Before the Tennessee Regulatory Authority. In the Matter of the Petition of Piedmont Natural Gas Company, Inc. to Implement a Margin Decoupling Tracker Rider and Related Energy Efficiency and Conservation Programs. On the Behalf of the Tennessee Attorney General, Consumer Advocate & Protection Division. Issues: revenue decoupling, energy efficiency program review, weather normalization.

176. Expert Testimony. Docket Number NG-0060. (2009). Before the Nebraska Public Service Commission. In the Matter of SourceGas Distribution, LLC Approval for a General Rate Increase. On the Behalf of the Nebraska Public Advocate. October 29, 2009. Issues: revenue decoupling, inflation trackers, infrastructure replacement riders, customer adjustment rider, weather normalization rider, weather normalization adjustments, estimation of normal weather for ratemaking purposes.

177. Expert Report and Deposition. Before the 23rd Judicial District Court, Parish of Assumption, State of Louisiana. On the Behalf of Dow Hydrocarbons and Resources, Inc. September 1, 2009. (Deposition, November 23-24, 2009). Issues: replacement and repair costs for underground salt cavern hydrocarbon storage.

178. Expert Testimony. D.P.U. 09-39. Before the Massachusetts Department of Public Utilities. (2009). Investigation Into the Propriety of Proposed Tariff Changes for Massachusetts Electric Company and Nantucket Electric Company (d./b./a. National Grid). On the Behalf of the Office of the Attorney General, Office of Ratepayer Advocacy. Issues: Revenue decoupling; infrastructure rider; performance-based regulation; inflation adjustment mechanisms; revenue distribution; and rate design.

179. Expert Testimony. D.P.U. 09-30. Before the Massachusetts Department of Public Utilities. (2009). In the Matter of Bay State Gas Company Request for Increase in Rates. On the Behalf of the Office of the Attorney General, Office of Ratepayer Advocacy. Issues: Revenue decoupling; target infrastructure replacement program rider; revenue distribution; and rate design.

180. Expert Testimony. Docket EO09030249. (2009). Before the New Jersey Board of Public Utilities. In the Matter of the Petition of Public Service Electric and Gas Company for Approval of a Solar Loan II Program and An Associated Cost Recovery Mechanism. On the Behalf of the Department of the Public Advocate, Division of Rate Counsel. Issues: solar energy market design, renewable portfolio standards, solar energy, and renewable financing/loan program design.

181. Expert Testimony. Docket EO0920097. (2009). Before the New Jersey Board of Public Utilities. In the Matter of the Verified Petition of Rockland Electric Company for Approval of an SREC-Based Financing Program and An Associated Cost Recovery Mechanism. On the Behalf of the Department of the Public Advocate, Division of Rate Counsel. Issues: solar energy market design; renewable energy portfolio standards; solar energy.

182. Expert Rebuttal Report. Civil Action No.: 2:07-CV-2165. (2009). Before the U.S. District Court, Western Division of Louisiana, Lake Charles Division. Prepared on the Behalf of the Transcontinental Pipeline Corporation. Issues: expropriation and industrial use of property.

183. Expert Testimony. Docket EO06100744. (2008). Before the New Jersey Board of Public Utilities. In the Matter of the Renewable Portfolio Standard – Amendments to the Minimum filing Requirements for Energy Efficiency, Renewable Energy, and Conservation Programs and For Electric Distribution Company Submittals of Filings in connection with Solar Financing (Atlantic City Electric Company). On the Behalf of the Department of the Public Advocate, Division of Rate Counsel. Issues: Solar energy market design; renewable energy portfolio standards; solar energy. (Rebuttal and Surrebuttal)

184. Expert Testimony. Docket EO08090840. (2008). Before the New Jersey Board of Public Utilities. In the Matter of the Renewable Portfolio Standard – Amendments to the Minimum filing Requirements for Energy Efficiency, Renewable Energy, and Conservation Programs and For Electric Distribution Company Submittals of Filings in connection with Solar Financing (Jersey Central Power & Light Company). On the Behalf of the

Department of the Public Advocate, Division of Rate Counsel. Issues: Solar energy market design; renewable energy portfolio standards; solar energy. (Rebuttal and Surrebuttal)

185. Expert Testimony. Docket UG-080546. (2008). Before the Washington Utilities and Transportation Commission. On the Behalf of the Washington Attorney General (Public Counsel Section). Issues: Rate Design, Cost of Service, Revenue Decoupling, Weather Normalization.

186. Congressional Testimony. (2008). Senate Republican Conference: Panel on Offshore Drilling in the Restricted Areas of the Outer Continental Shelf. September 18, 2008.

187. Expert Testimony. Appeal Number 2007-125 and 2007-299. (2008). Before the Louisiana Tax Commission. On the Behalf of Jefferson Island Storage and Hub, LLC (AGL Resources). Issues: Valuation Methodologies, Underground Storage Valuation, LTC Guidelines and Policies, Public Purpose of Natural Gas Storage. July 15, 2008 and August 20, 2008.

188. Expert Testimony. Docket Number 07-057-13. (2008). Before the Utah Public Service Commission. In the Matter of the Application of Questar Gas Company to File a General Rate Case. On the Behalf of the Utah Committee of Consumer Services. Issues: Cost of Service, Rate Design. August 18, 2008 (Direct, Rebuttal, Surrebuttal).

189. Rulemaking Testimony. (2008). Before the Louisiana Tax Commission. Examination of Replacement Cost Tables, Depreciation and Useful Lives for Oil and Gas Properties. Chapter 9 (Oil and Gas Properties) Section. August 5, 2008.

190. Legislative Testimony. (2008). Examination of Proposal to Change Offshore Natural Gas Severance Taxes (HB 326 and Amendments). Joint Finance and Appropriations Committee of the Alabama Legislature. March 13, 2008.

191. Public Testimony. (2007). Issues in Environmental Regulation. Testimony before Gubernatorial Transition Committee on Environmental Regulation (Governor-Elect Bobby Jindal). December 17, 2007.

192. Public Testimony. (2007). Trends and Issues in Alternative Energy: Opportunities for Louisiana. Testimony before Gubernatorial Transition Committee on Natural Resources (Governor-Elect Bobby Jindal). December 13, 2007.

193. Expert Report and Recommendation: Docket Number S-30336 (2007). Before the Louisiana Public Service Commission. In re: Entergy Gulf States, Inc. Application for Approval of Advanced Metering Pilot Program. Issues: pilot program for demand response programs and advanced metering systems.

194. Expert Testimony. Docket EO07040278 (2007). Before the New Jersey Board of Public Utilities. In the Matter of the Petition of Public Service Electric & Gas Company for Approval of a Solar Energy Program and An Associated Cost Recovery Mechanism. On the Behalf of the Department of the Public Advocate, Division of Rate Counsel. Issues: renewable energy market development, solar energy development, SREC markets, rate impact analysis, cost recovery issues.

195. Expert Testimony: Docket Number 05-057-T01 (2007). Before the Utah Public Service

Commission. In the Matter of: Joint Application of Questar Gas Company, the Division of Public Utilities, and Utah Clean Energy for Approval of the Conservation Enabling Tariff Adjustment Options and Accounting Orders. On the behalf of the Utah Committee of Consumer Services. Issues: Revenue Decoupling, Demand-side Management; Energy Efficiency policies. (Direct, Rebuttal, and Surrebuttal Testimony)

196. Expert Testimony (Non-sworn rulemaking testimony) Docket Number RR-2008, (2007). Before the Louisiana Tax Commission. In re: Commission Consideration of Amendment and/or Adoption of Tax Commission Real/Personal Property Rules and Regulations. Issues: Louisiana oil and natural gas production trends, appropriate cost measures for wells and subsurface property, economic lives and production decline curve trends.

197. Expert Report, Recommendation, and Proposed Rule: Docket Number R-29213 & 29213-A, ex parte, (2007). Before the Louisiana Public Service Commission. In re: In re: Investigation to determine if it is appropriate for LPSC jurisdictional electric utilities to provide and install time-based meters and communication devices for each of their customers which enable such customers to participate in time-based pricing rate schedules and other demand response programs. On the behalf of the Louisiana Public Service Commission Staff. Report and Recommendation. Issues: demand response programs, advanced meter systems, cost recovery issues, energy efficiency issues, regulatory issues.

198. Expert Report, Recommendation, and Proposed Rule: Docket Number R-29712, ex parte, (2007) Before the Louisiana Public Service Commission. In re: Investigation into the ratemaking and generation planning implications of nuclear construction in Louisiana. On the behalf of the Louisiana Public Service Commission Staff. Report and Recommendation. Issues: nuclear cost power plant development, generation planning issues, and cost recovery issues.

199. Expert Testimony, Case Number U-14893, (2006). Before the Michigan Public Service Commission. In the Matter of SEMCO Energy Gas Company for Authority to Redesign and Increase Its Rates for the Sale and Transportation of Natural Gas In its MPSC Division and for Other Relief. On the behalf of the Michigan Attorney General. Issues: Rate Design, revenue decoupling, financial analysis, demand-side management program and energy efficiency policy. (Direct and Rebuttal Testimony).

200. Expert Report, Recommendation, and Proposed Rule: Docket Number R-29380, ex parte, (2006). Before the Louisiana Public Service Commission. In re: An Investigation Into the Ratemaking and Generation Planning Implications of the U.S. EPA Clean Air Interstate Rule. On the behalf of the Louisiana Public Service Commission Staff. Report and Recommendation. Issues: environmental regulation and cost recovery; allowance allocations and air credit markets; ratepayer impacts of new environmental regulations.

201. Expert Affidavit Before the Louisiana Tax Commission (2006). On behalf of ANR Pipeline, Tennessee Gas Transmission and Southern Natural Gas Company. Issues: Competitive nature of interstate and intrastate transportation services.

202. Expert Affidavit Before the 19th Judicial District Court (2006). Suit Number 491, 453 Section 26. On behalf of Transcontinental Pipeline Corporation, et.al. Issues: Competitive

nature of interstate and intrastate transportation services.

203. Expert Testimony: Docket Number 05-057-T01 (2006). Before the Utah Public Service Commission. In the Matter of: Joint Application of Questar Gas Company, the Division of Public Utilities, and Utah Clean Energy for Approval of the Conservation Enabling Tariff Adjustment Options and Accounting Orders. On the behalf of the Utah Committee of Consumer Services. Issues: Revenue Decoupling, Demand-side Management; Energy Efficiency policies. (Rebuttal and Supplemental Rebuttal Testimony)

204. Legislative Testimony (2006). Senate Committee on Natural Resources. Senate Bill 655 Regarding Remediation of Oil and Gas Sites, Legacy Lawsuits, and the Deterioration of State Drilling.

205. Expert Report: Rulemaking Docket (2005). Before the New Jersey Bureau of Public Utilities. In re: Proposed Rulemaking Changes Associated with New Jersey's Renewable Portfolio Standard. Expert Report. The Economic Impacts of New Jersey's Proposed Renewable Portfolio Standard. On behalf of the New Jersey Office of Ratepayer Advocate. Issues: Renewable Portfolio Standards, rate impacts, economic impacts, technology cost forecasts.

206. Expert Testimony: Docket Number 2005-191-E. (2005). Before the South Carolina Public Service Commission. On behalf of NewSouth Energy LLC. In re: General Investigation Examining the Development of RFP Rules for Electric Utilities. Issues: Competitive bidding; merchant development. (Direct and Rebuttal Testimony).

207. Expert Testimony: Docket No. 05-UA-323. (2005). Before the Mississippi Public Service Commission. On the behalf of Calpine Corporation. In re: Entergy Mississippi's Proposed Acquisition of the Attala Generation Facility. Issues: Asset acquisition; merchant power development; competitive bidding.

208. Expert Testimony: Docket Number 050045-EI and 050188-EI. (2005). Before the Florida Public Service Commission. On the behalf of the Citizens of the State of Florida. In re: Petition for Rate Increase by Florida Power & Light Company. Issues: Load forecasting; O&M forecasting and benchmarking; incentive returns/regulation.

209. Expert Testimony (non-sworn, rulemaking): Comments on Decreased Drilling Activities in Louisiana and the Role of Incentives. (2005). Louisiana Mineral Board Monthly Docket and Lease Sale. July 13, 2005

210. Legislative Testimony (2005). Background and Impact of LNG Facilities on Louisiana. Joint Meeting of Senate and House Natural Resources Committee. Louisiana Legislature. May 19, 2005.

211. Public Testimony. Docket No. U-21453. (2005). Technical Conference before the Louisiana Public Service Commission on an Investigation for a Limited Industrial Retail Choice Plan.

212. Expert Testimony: Docket No. 2003-K-1876. (2005). On Behalf of Columbia Gas Transmission. Expert Testimony on the Competitive Market Structure for Gas Transportation Service in Ohio. Before the Ohio Board of Tax Appeals.

213. Expert Report and Testimony: Docket No. 99-4490-J, *Lafayette City-Parish Consolidated*

Government, et. al. v. Entergy Gulf States Utilities, Inc. et. al. (2005, 2006). On behalf of the City of Lafayette, Louisiana and the Lafayette Utilities Services. Expert Rebuttal Report of the Harborfront Consulting Group Valuation Analysis of the LUS Expropriation. Filed before 15th Judicial District Court, Lafayette, Louisiana.

214. Expert Testimony: ANR Pipeline Company v. Louisiana Tax Commission (2005), Number 468,417 Section 22, 19th Judicial District Court, Parish of East Baton Rouge, State of Louisiana Consolidated with Docket Numbers: 480,159; 489,776;480,160; 480,161; 480,162; 480,163; 480,373; 489,776; 489,777; 489,778;489,779; 489,780; 489,803; 491,530; 491,744; 491,745; 491,746; 491,912;503,466; 503,468; 503,469; 503,470; 515,414; 515,415; and 515,416. In re: Market structure issues and competitive implications of tax differentials and valuation methods in natural gas transportation markets for interstate and intrastate pipelines.

215. Expert Report and Recommendation: Docket No. U-27159. (2004). On Behalf of the Louisiana Public Service Commission Staff. Expert Report on Overcharges Assessed by Network Operator Services, Inc. Before the Louisiana Public Service Commission.

216. Expert Testimony: Docket Number 2004-178-E. (2004). Before the South Carolina Public Service Commission. On behalf of Columbia Energy LLC. In re: Rate Increase Request of South Carolina Electric and Gas. (Direct and Surrebuttal Testimony)

217. Expert Testimony: Docket Number 040001-EI. (2004). Before the Florida Public Service Commission. On behalf of Power Manufacturing Systems LLC, Thomas K. Churbuck, and the Florida Industrial Power Users Group. In re: Fuel Adjustment Proceedings; Request for Approval of New Purchase Power Agreements. Company examined: Florida Power & Light Company.

218. Expert Affidavit: Docket Number 27363. (2004). Before the Public Utilities Commission of Texas. Joint Affidavit on Behalf of the Cities of Texas and the Staff of the Public Utilities Commission of Texas Regarding Certified Issues. In Re: Application of Valor Telecommunications, L.P. For Authority to Establish Extended Local Calling Service (ELCS) Surcharges For Recovery of ELCS Surcharge.

219. Expert Report and Testimony. Docket 1997-4665-PV, 1998-4206-PV, 1999-7380-PV, 2000-5958-PV, 2001-6039-PV, 2002-64680-PV, 2003-6231-PV. (2003) Before the Kansas Board of Tax Appeals. (2003). In the Matter of the Appeals of CIG Field Services Company from orders of the Division of Property Valuation. On the Behalf of CIG Field Services. Issues: the competitive nature of natural gas gathering in Kansas.

220. Expert Report and Testimony: Docket Number U-22407. Before the Louisiana Public Service Commission (2002). On the Behalf of the Louisiana Public Service Commission Staff. Company examined: Louisiana Gas Services, Inc. Issues: Purchased Gas Acquisition audit, fuel procurement and planning practices.

221. Expert Testimony: Docket Number 000824-EI. Before the Florida Public Service Commission. (2002). On the Behalf of the Citizens of the State of Florida. Company examined: Florida Power Corporation. Issues: Load Forecasts and Billing Determinants for the Projected Test Year.

222. Public Testimony: Louisiana Board of Commerce and Industry (2001). Testimony on the Economic Impacts of Merchant Power Generation.

223. Expert Testimony: Docket Number 24468. (2001). On the Behalf of the Texas Office of Public Utility Counsel. Public Utility Commission of Texas Staff's Petition to Determine Readiness for Retail Competition in the Portion of Texas Within the Southwest Power Pool. Company examined: AEP-SWEPCO.

224. Expert Report. (2001) On Behalf of David Liou and Pacific Richland Products, Inc. to Review Cogeneration Issues Associated with Dupont Dow Elastomers, L.L.C. (DDE) and the Dow Chemical Company (Dow).

225. Expert Testimony: Docket Number 01-1049, Docket Number 01-3001. (2001) On behalf the Nevada Office of Attorney General, Bureau of Consumer Protection. Petition of Central Telephone Company-Nevada D/b/a Sprint of Nevada and Sprint Communications L.P. for Review and Approval of Proposed Revised Performance Measures and Review and Approval of Performance Measurement Incentive Plans. Before the Public Utilities Commission of Nevada.

226. Expert Affidavit: Multiple Dockets (2001). Before the Louisiana Tax Commission. On the Behalf of Louisiana Interstate Pipeline Companies. Testimony on the Competitive Nature of Natural Gas Transportation Services in Louisiana.

227. Expert Affidavit before the Federal District Court, Middle District of Louisiana (2001). Issues: Competitive Nature of the Natural Gas Transportation Market in Louisiana. On behalf of a Consortium of Interstate Natural Gas Transportation Companies.

228. Public Testimony: Louisiana Board of Commerce and Industry (2001). Testimony on the Economic and Ratepayer Benefits of Merchant Power Generation and Issues Associated with Tax Incentives on Merchant Power Generation and Transmission.

229. Expert Testimony: Docket Number 01-1048 (2001). Before the Public Utilities Commission of Nevada. On the Behalf of the Nevada Office of the Attorney General, Bureau of Consumer Protection. Company analyzed: Nevada Bell Telephone Company. Issues: Statistical Issues Associated with Performance Incentive Plans.

230. Expert Testimony: Docket 22351 (2001). Before the Public Utility Commission of Texas. On the Behalf of the City of Amarillo. Company analyzed: Southwestern Public Service Company. Issues: Unbundled cost of service, affiliate transactions, load forecasting.

231. Expert Testimony: Docket 991779-EI (2000). Before the Florida Public Service Commission. On the Behalf of the Citizens of the State of Florida. Companies analyzed: Florida Power & Light Company; Florida Power Corporation; Tampa Electric Company; and Gulf Power Company. Issues: Competitive Nature of Wholesale Markets, Regional Power Markets, and Regulatory Treatment of Incentive Returns on Gains from Economic Energy Sales.

232. Expert Testimony: Docket 990001-EI (1999). Before the Florida Public Service Commission. On the Behalf of the Citizens of the State of Florida. Companies analyzed: Florida Power & Light Company; Florida Power Corporation; Tampa Electric Company; and Gulf Power Company. Issues: Regulatory Treatment of Incentive Returns on Gains

from Economic Energy Sales.

233. Expert Testimony: Docket 950495-WS (1996). Before the Florida Public Service Commission. On the Behalf of the Citizens of the State of Florida. Company analyzed: Southern States Utilities, Inc. Issues: Revenue Repression Adjustment, Residential and Commercial Demand for Water Service.

234. Legislative Testimony. Louisiana House of Representatives, Special Subcommittee on Utility Deregulation. (1997). On Behalf of the Louisiana Public Service Commission Staff. Issue: Electric Restructuring.

235. Expert Testimony: Docket 940448-EG -- 940551-EG (1994). Before the Florida Public Service Commission. On the Behalf of the Legal Environmental Assistance Foundation. Companies analyzed: Florida Power & Light Company; Florida Power Corporation; Tampa Electric Company; and Gulf Power Company. Issues: Comparison of Forecasted Cost-Effective Conservation Potentials for Florida.

236. Expert Testimony: Docket 920260-TL, (1993). Before the Florida Public Service Commission. On the Behalf of the Florida Public Service Commission Staff. Company analyzed: BellSouth Communications, Inc. Issues: Telephone Demand Forecasts and Empirical Estimates of the Price Elasticity of Demand for Telecommunication Services.

237. Expert Testimony: Docket 920188-TL, (1992). Before the Florida Public Service Commission. On the Behalf of the Florida Public Service Commission Staff. Company analyzed: GTE-Florida. Issues: Telephone Demand Forecasts and Empirical Estimates of the Price Elasticity of Demand for Telecommunication Services.

ACADIAN
CONSULTING GROUP

Affordability Issues in Pepco Base Rate Case

Prepared on the behalf of the District of Columbia, Office of the People's Counsel

David E. Dismukes, Ph.D.
Acadian Consulting Group

January 12, 2024

Introduction

Study purpose and findings

The Acadian Consulting Group, LLC ("ACG") has been asked by the District of Columbia, Office of the Peoples Counsel ("OPC) to **examine affordability issues in the District.**

The purpose of this analysis is **to examine electricity affordability and how that has changed since the approval of Pepco's multi-year rate plan pilot ("MRP Pilot") program.** The analysis here **focusses on electricity affordability measures at both aggregate and detailed census/zip code levels information.**

The analysis finds that <u>Pepco's consistent and large rate increases had jeopardized electricity affordability</u>, particularly for those least advantaged communities in the District. **<u>The Commission's policies</u>** of allocating ever increasing shares of these rate increases to residential customers **<u>has exacerbated these affordability challenges</u>.**

While Pepco does have low-income support programs, these **programs fail to reach an overwhelming portion of low-income households/residents**, **nor do they offset the increases** that have arisen from the MRP Pilot.

Recommendations

ACG makes the following recommendations:

- **Do not approve the proposed multi-year rate plan ("MYP")**. The current MRP Pilot has done nothing but make electricity more expensive in the District.
- **Limit Pepco's proposed annual capital expenditures** to levels that are more sustainable and consistent with affordability concerns.
- Require Pepco to **regularly examine and file affordability analyses**.
- **Review the Pepco's low-income proposals** for:

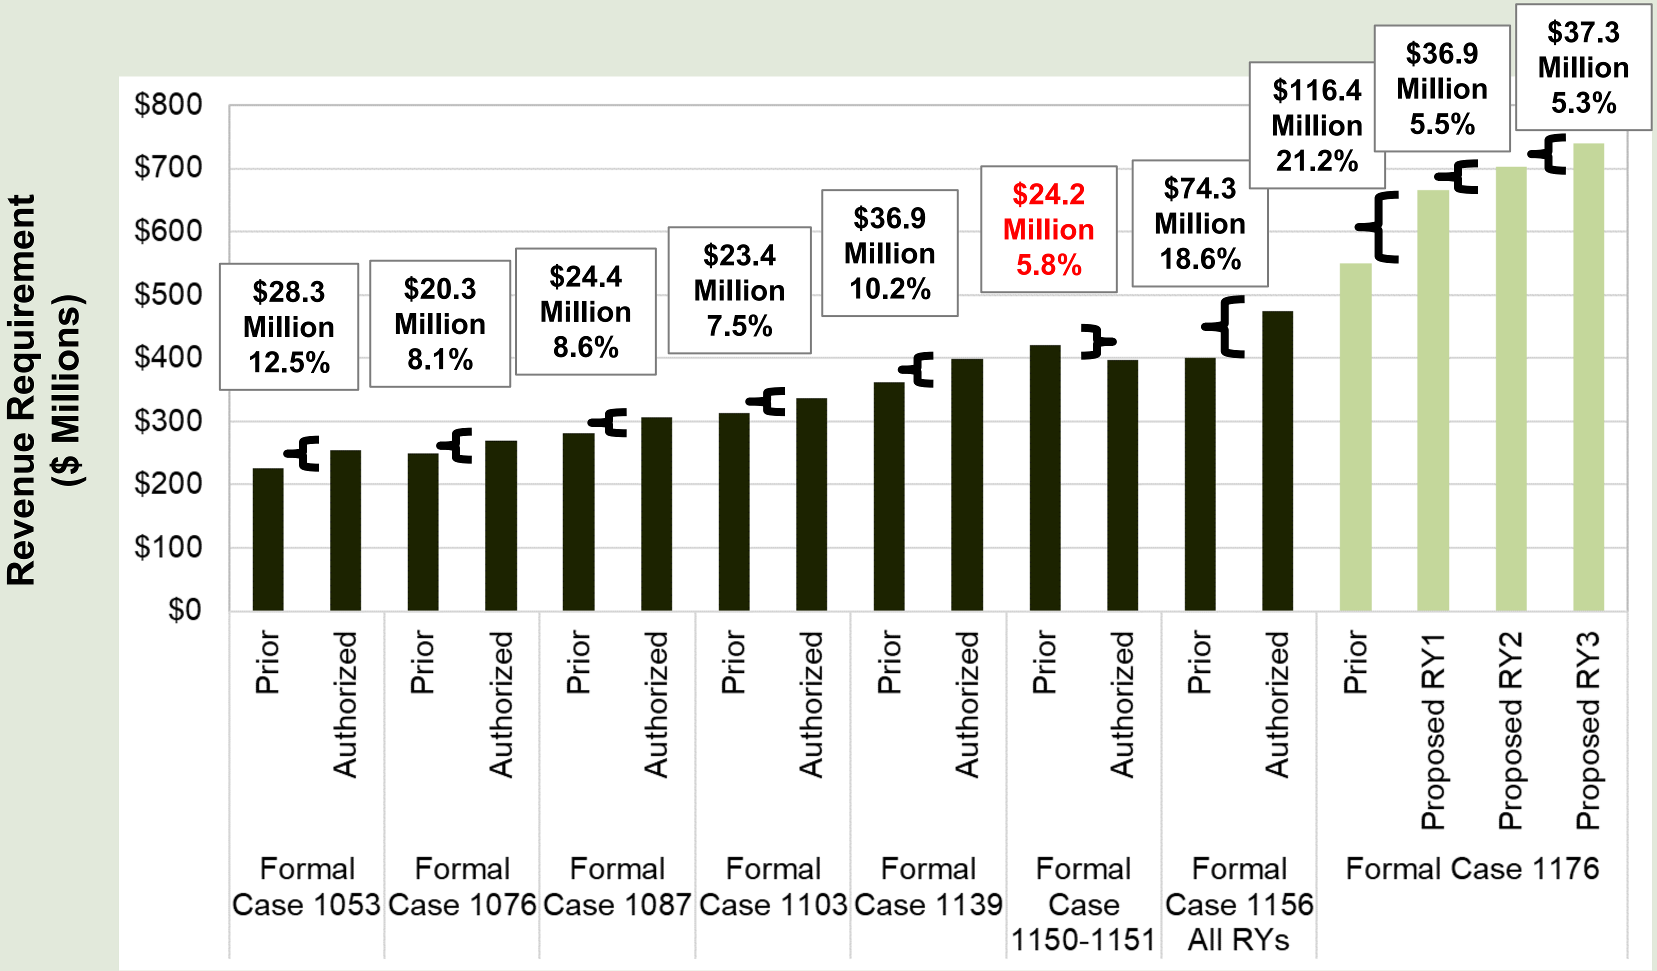
  (a) potential modifications that **expand coverage** to a larger number of eligible households and

  (b) **means test and scale financial assistance levels** to assure adequacy, minimize adverse rate impacts on other supporting customers, and to get the "biggest bang for the buck" in low-income assistance.

Pepco's rate increases are harming ratepayers

Historic PEPCO revenue requirements with proposed MYP

PEPCO proposes **two-year rate increases of $74.3 million** ~ 85 percent greater than rates prior to FC 1156 (2019) and **double rate levels in FC 1053 (2006).**



Growth in residential rates relative to inflation

PEPCO **residential rates have far outpaced inflation** at **over nine percent per year**.

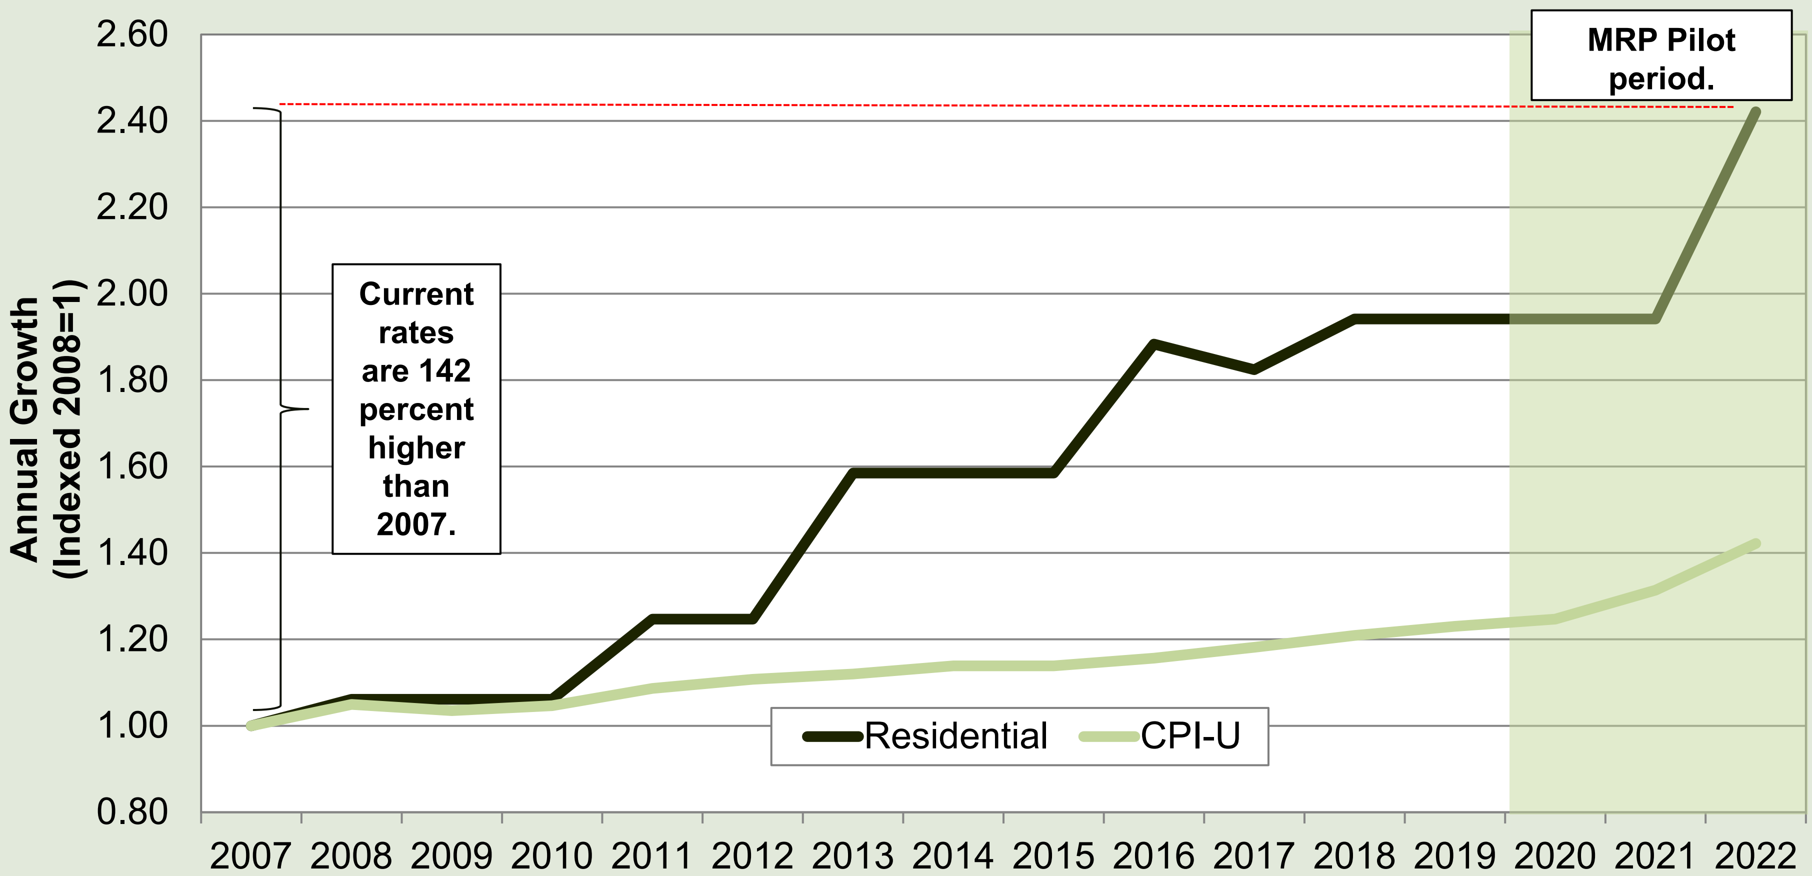


Exhibit OPC (A)-2
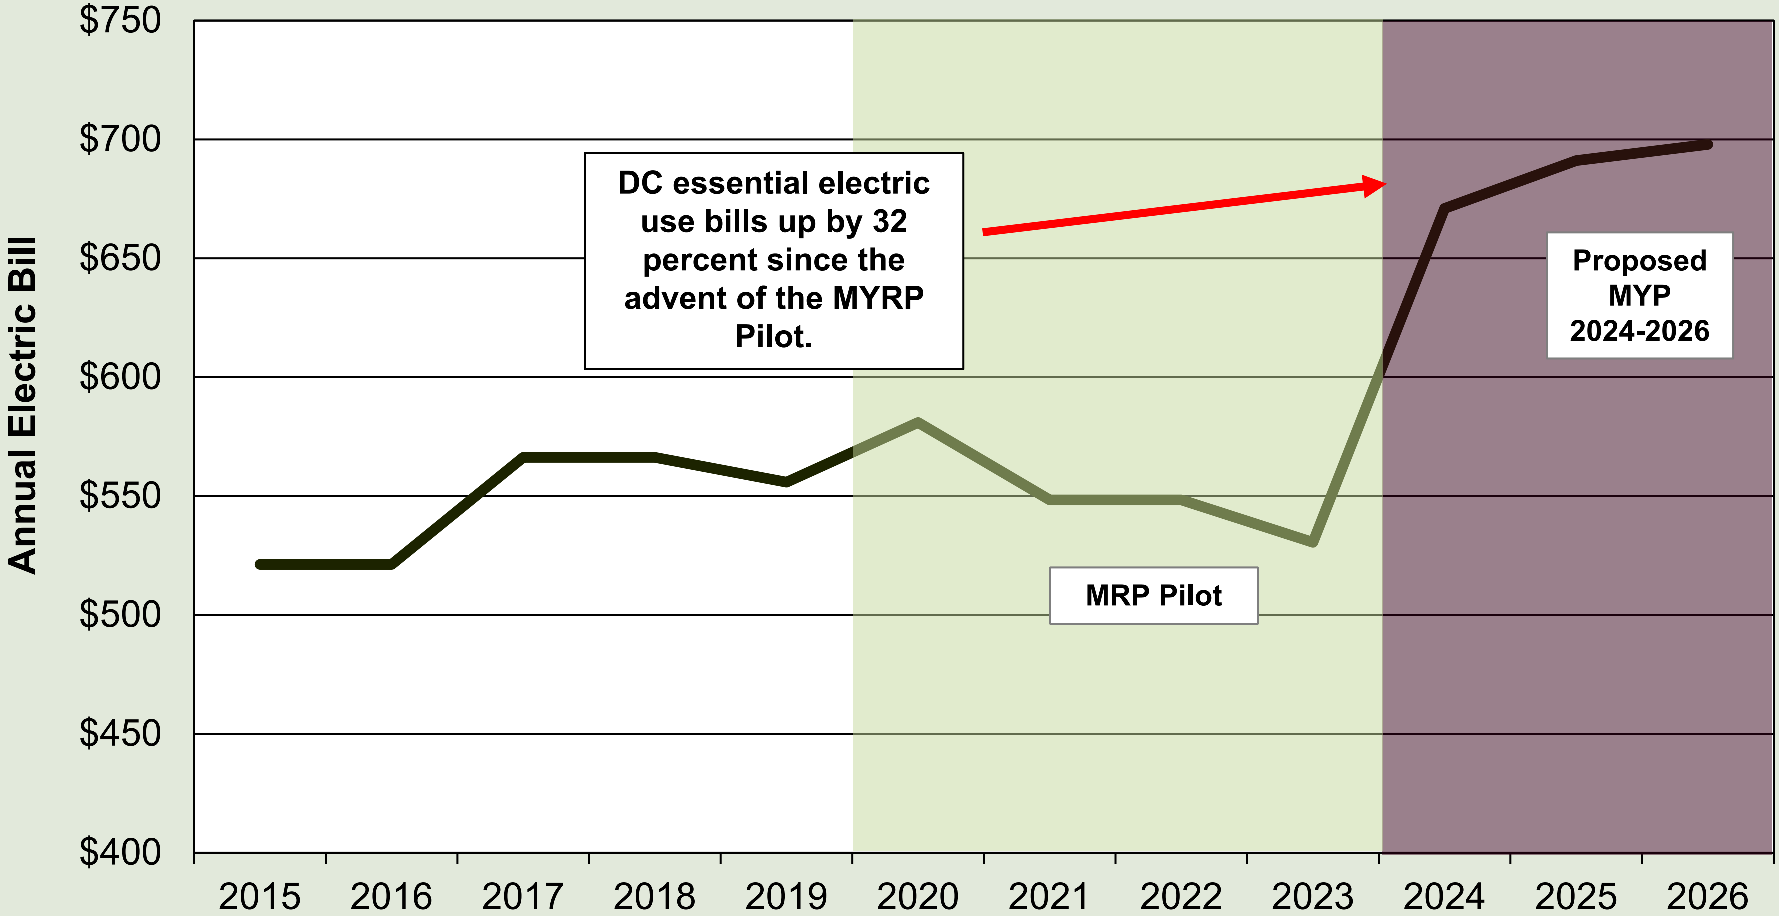
Formal Case No. 1176
David E. Dismukes, Ph.D.
Page 8 of 39

PEPCO residential essential electric bills

The **cost of essential electricity has skyrocketed** because of **Pepco's significant MYRP related rate increases**.



Source: FC 1176 OPC DR 3-19 and PEPCO (E)-5, baseline usage estimated by Brattle Study at 337 kWh per month.

Historic and proposed residential class revenue responsibilities

PEPCO proposes **full cost-of-service residential rates** that will increase by **80 percent** (three-year MYRP) or **2.30 times the overall proposed 34.84 percent increase**.

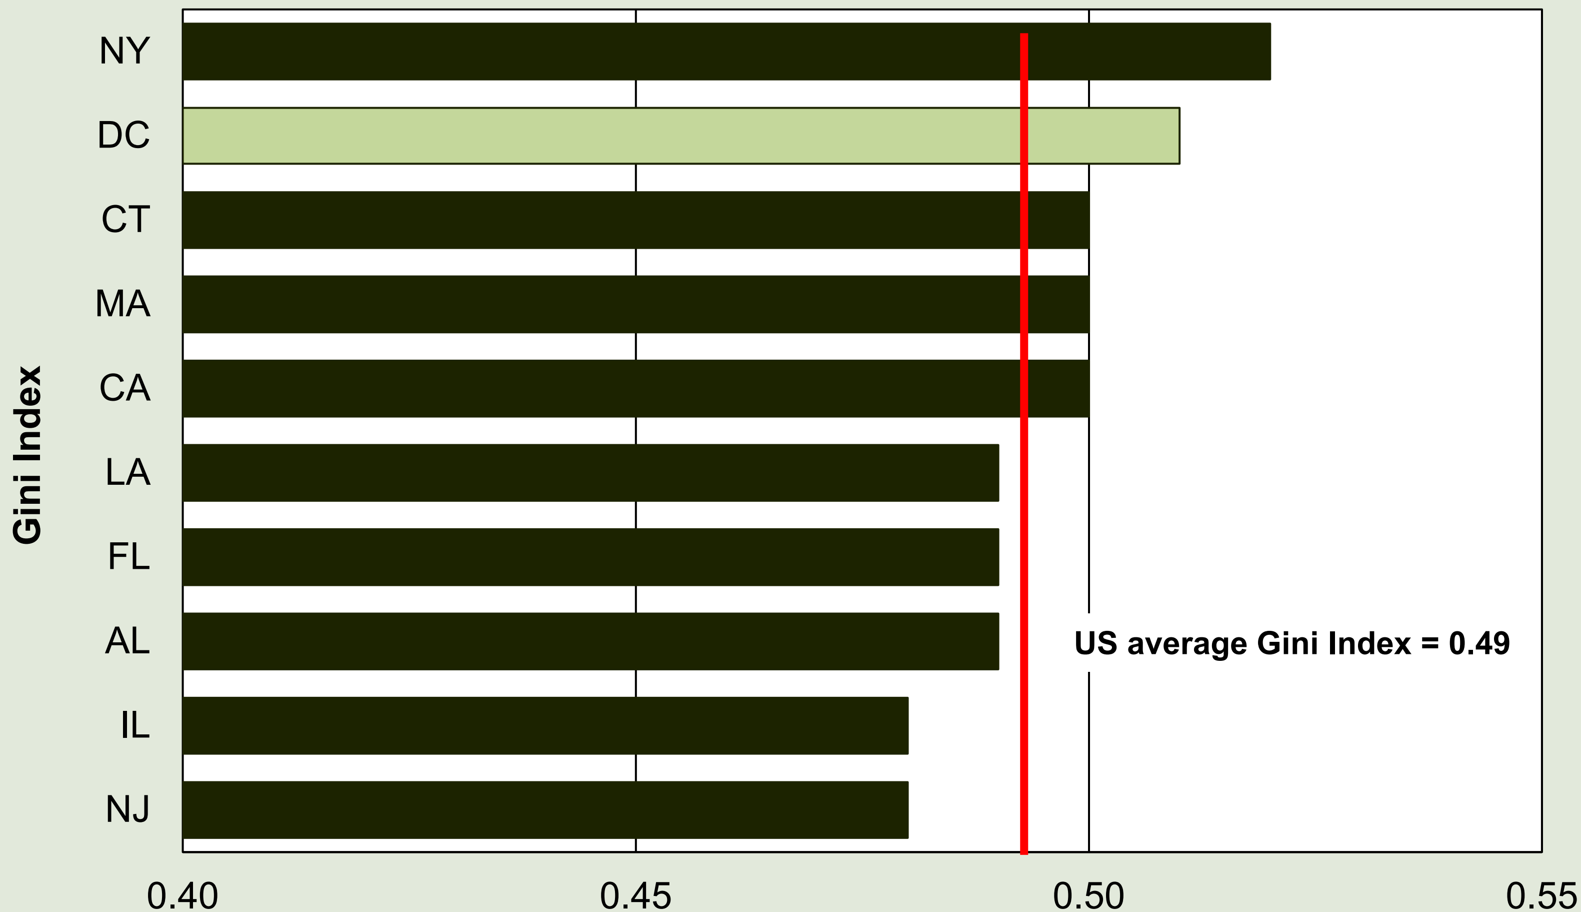
	Relative Rate of Return	Rate Increase		
Case No.	Total Residential	System Average	Total Residential	Relative Increase
FC 1053	-0.48	12.50%	13.33%	1.07
FC 1076	-0.47	7.94%	17.52%	2.21
FC 1087	-0.54	8.64%	21.40%	2.48
FC 1103	-0.41	7.48%	17.56%	2.35
FC 1139	-0.60	10.20%	9.25%	0.91
FC 1150/1151	-0.75	-6.05%	-3.02%	-0.50
FC 1156	-1.00	17.34%	14.00%	0.81
FC 1176	**-0.68**	**34.84%**	**80.14%**	**2.30**

Note - past residential rates increases **have not resulted in any improvement in the relative rate of return** associated with residential rates.

The District has an affordability challenge

DC income inequality is the worst in the U.S. (Gini Index = 2022)

The **District has one of the highest measures of income inequality** in the nation.



Note: A Gini Index is the difference between the Lorenz curve (the observed cumulative income distribution) and a perfectly equal income distribution. A score of 0 reflects perfect income equality and 1 indicates perfect "inequality" where one person holds all wealth.

Source: U.S. Census, Statista Gini Coefficient in the United States, 2022

D.C. population distribution by federal poverty level, 2022

The District has a considerable number of residents living below the federal poverty level ("FPL"): **23 percent live at our below 200 percent of the FPL.**

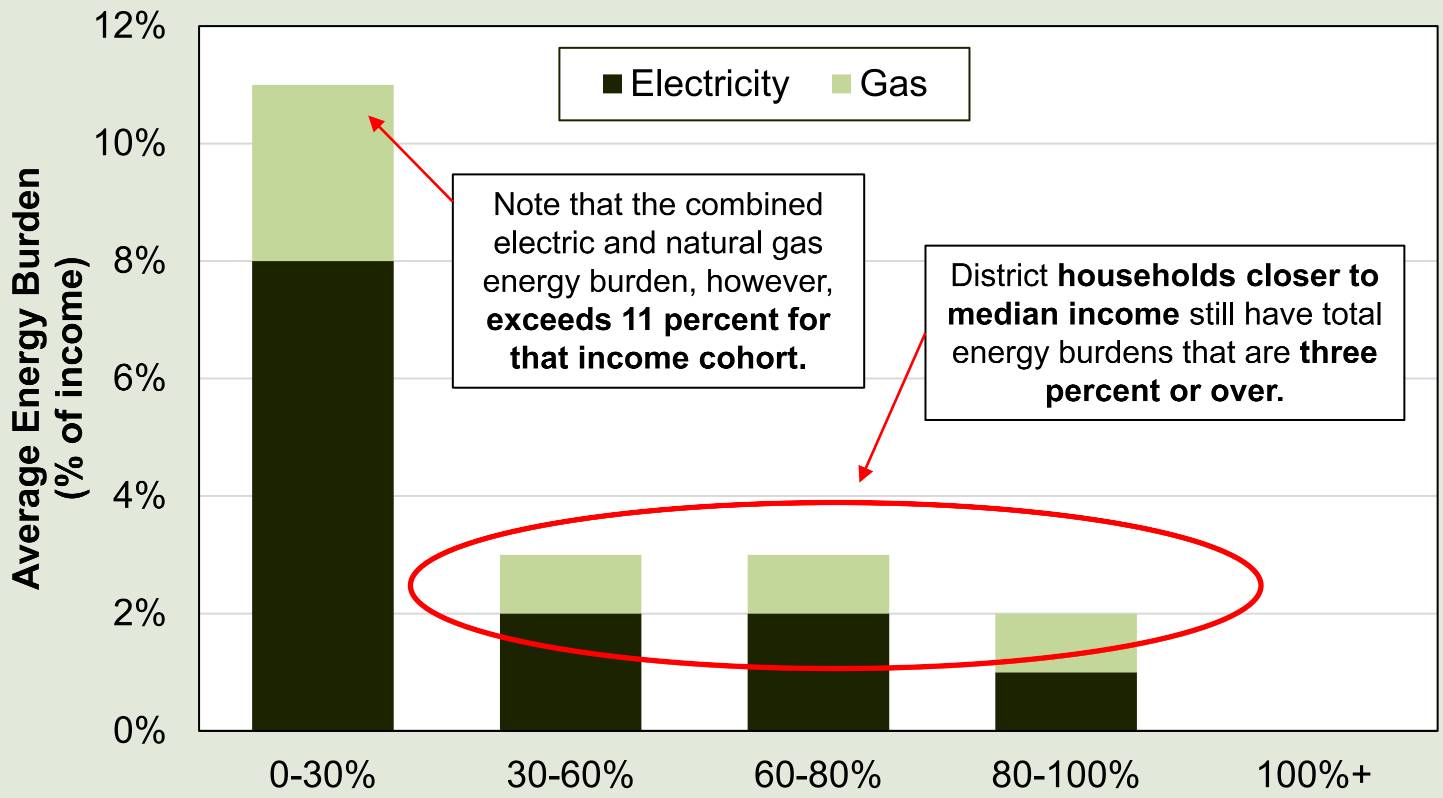
Page 13 of 39

LEAD Tool analysis of DC energy affordability

A recent Low-Income Energy Affordability Tool (LEAD) analysis found that DC low-income households (less than 30 percent of overall median income) have an **average electric energy burden of eight percent – well above a six percent burdensome threshold.**



Source: Low-Income Energy Affordability Data Tool (LEAD).

Measuring Affordability: Analysis and Practice

Affordability indices in utility regulation

Energy affordability is increasingly becoming an important issue in regulatory policy making. Several states require affordability calculations, and some are regularly developing their own estimates. Several non-governmental organizations and research groups are also engaged in this effort.

- The **California Public Utilities Commission (CPUC)** developed the state's first energy affordability metric that tracks affordability for essential service level (electric, gas, water, and communications, see Order 18-07-006, 2018). California adopted the following three metrics: Affordability Ratio, Hours-at-Minimum-Wage, and Socioeconomic Vulnerability Index. The third phase of the order is focused on analyzing strategies to mitigate future rate increases based on the affordability metrics calculated.
- The **Connecticut Green Bank** mapped household energy and transportation affordability in Connecticut in 2020. The report and mapping utilizes a metric that measures the effect of energy and transportation costs on household income by census tract. The report calculated that households earning less than 50 percent of the State Median Income had an annual building energy affordability gap of $1,010. This gap represents the difference between affordable level of spending in a census tract and actual levels of spending.

Sources: California Public Utilities Commission, Rulemaking 18-07-006, Jule 12, 2018.
Connecticut Green Bank, Mapping Household Energy and Transportation in Connecticut, October 2020.

Affordability indices in utility regulation (continued)

- The **Pennsylvania Utility Commission (PUC)** examined home energy burdens for low-income Pennsylvanians in its Home Energy Affordability 2019 report. The study found a wide disparity in the average percent of household income spent on natural gas and electric services by Customer Assistance Programs (CAP) customers and non-CAP customers. CAP customers with gas heating and electric non-heating had a combined average energy burden of 12 to 14 percent or with electric heat 8 to 10 percent. In contrast, non-CAP customers had an average energy burden of 4 percent for gas heating and electric non-heating or 4 percent for electric heating.
- **Legal Action Chicago, Nicor Gas Company Rate Case** (Docket No. 23-0066, 2023) created a series of metrics and indexes that measure the impact of natural gas bills on low-income customers. Legal Action Chicago found that NICOR burdens fell between 8 to 17 percent of income for households with income less than 50 percent of the Federal Poverty Line (FPL). In comparison, at incomes between 100 to 150 percent of FPL, burdens are between 3 and 4 percent.
- **Synapse Energy Economics** analyzed low-income energy burden by county in its Maine Low-Income Home Energy Burden Study 2019. The report calculates affordability ratios for various income levels and found that the average home energy burden for low-income households is 19 percent while the mean energy burden for all households in the state is 6 percent.

Sources: Home Energy Affordability for Low-Income Customers in Pennsylvania, January 2019, Pennsylvania Public Utility Commission.
Direct Testimony of Roger D. Colton, Legal Action of Chicago, May 2, 2023. Maine Low-Income Home Energy Burden Study, Synapse Energy Economics, June 3, 2019.

Affordability indices in utility regulation (continued)

- The **New York Public Service Commission** (Case 14-M-0565, 2016) analyzed utility affordability for low-income households and adopted regulatory policy framework to address these customers' needs, including an energy burden target of 5 percent for all 2.3 million low-income households in New York.
- **West Virginia American Water** (Rate Case No. 23-0383-W-42T) submitted an "Affordability Index for Basic Water Service" (estimated at 40 gallons of water per household member per day). The index showed that customers who spend more than 2 percent of their income on Basic Water Service represent 45 percent of the total customer population and have an income that is generally less than $35,000 per year.
- **National Consumer Law Center** conducted a Utility Bill Affordability Study in 2020 for Colorado. The study analyzed affordability program designs, income, and cost of living for families at or below 200 percent of the Federal Poverty Level. The study showed that if an additional 70 cents per month per customer were added to increase funds for the Percentage of Income Payment Plan (PIPP), a 3 percent target energy burden would be reached for all customers. For example, the undiscounted electricity burden for a Black Hills Electric customer who is single and makes minimum wage is 7.8 percent compared to the discounted electricity burden of 3 percent.

Sources: Proceeding on Motion of the Commission to Examine Programs to Address Energy Affordability, May 20, 2016, Case 14-M-0565.
Direct Testimony of Charles B. Rea Case No. 23-0383-W-42T. National Consumer Law Center "Utility Bill Affordability in Colorado" October 2020.

Affordability indices in utility regulation (continued)

- The **Energy Information Administration (EIA)** analyzed household energy insecurity in 2020 across the United States. The EIA found that nearly 26 percent of all households in the Mid Atlantic suffer from some form of energy insecurity, including approximately 18 percent of households reporting reducing or forgoing food or medicine to pay energy costs, and approximately 11.2 percent of households reporting leaving home at an unhealthy temperature. EIA also found that energy insecurity was prevalent even up to households earning above $60k a year (approximately 20 percent).
- The **Department of Public Utilities (DPU)** in Massachusetts, in D.P.U. 22-22, required ENSTAR to provide a "detailed household economic burden index analysis evaluating residential energy electric utility customer bills as percentage of household income by county and to provide the summary results of detailed household burden index analysis". The Department required three income groups in the analysis: 50 percent of FPL, 100 percent of FPL, and 200 percent of FPL. The Department also issued directives to National Grid and Until to perform similar burden analysis in their 2022 Annual Returns Report to the Department.

Sources: Energy Information Administration (EIA) Household Energy Insecurity 2020 Report, March 2023.
Order D.P.U. 22-22, Petition of NSTAR Electric Company, doing business as Eversource Energy, pursuant to G.L. c. 164, § 94 and 220 CMR 5.00, for Approval of a General Increase in Base Distribution Rates for Electric Service and a Performance Based Ratemaking Plan, November 30, 2022.

D.C. Affordability Analysis

Energy affordability ratio

- The **energy affordability ratio** measures the percentage of a household income that is used to pay for electricity and natural gas**.** While academic literature has focused on total utility affordability, for purposes of this analysis only electric and natural gas rates in the District are examined.
- This ratio, or quotient, has “**average” energy expenditures** as the numerator **and income less rent (housing costs)** as the denominator.
- The data used includes:

  Income: Disposable household income based on two groups (15th and 20th income percentiles) using American Community Survey Economic Characteristics DC Census Tract data.

  Rent: Average rent in the District was calculate based on information for 15th and 20th income percentiles using American Community Survey Economic Characteristics DC Census Tract data.

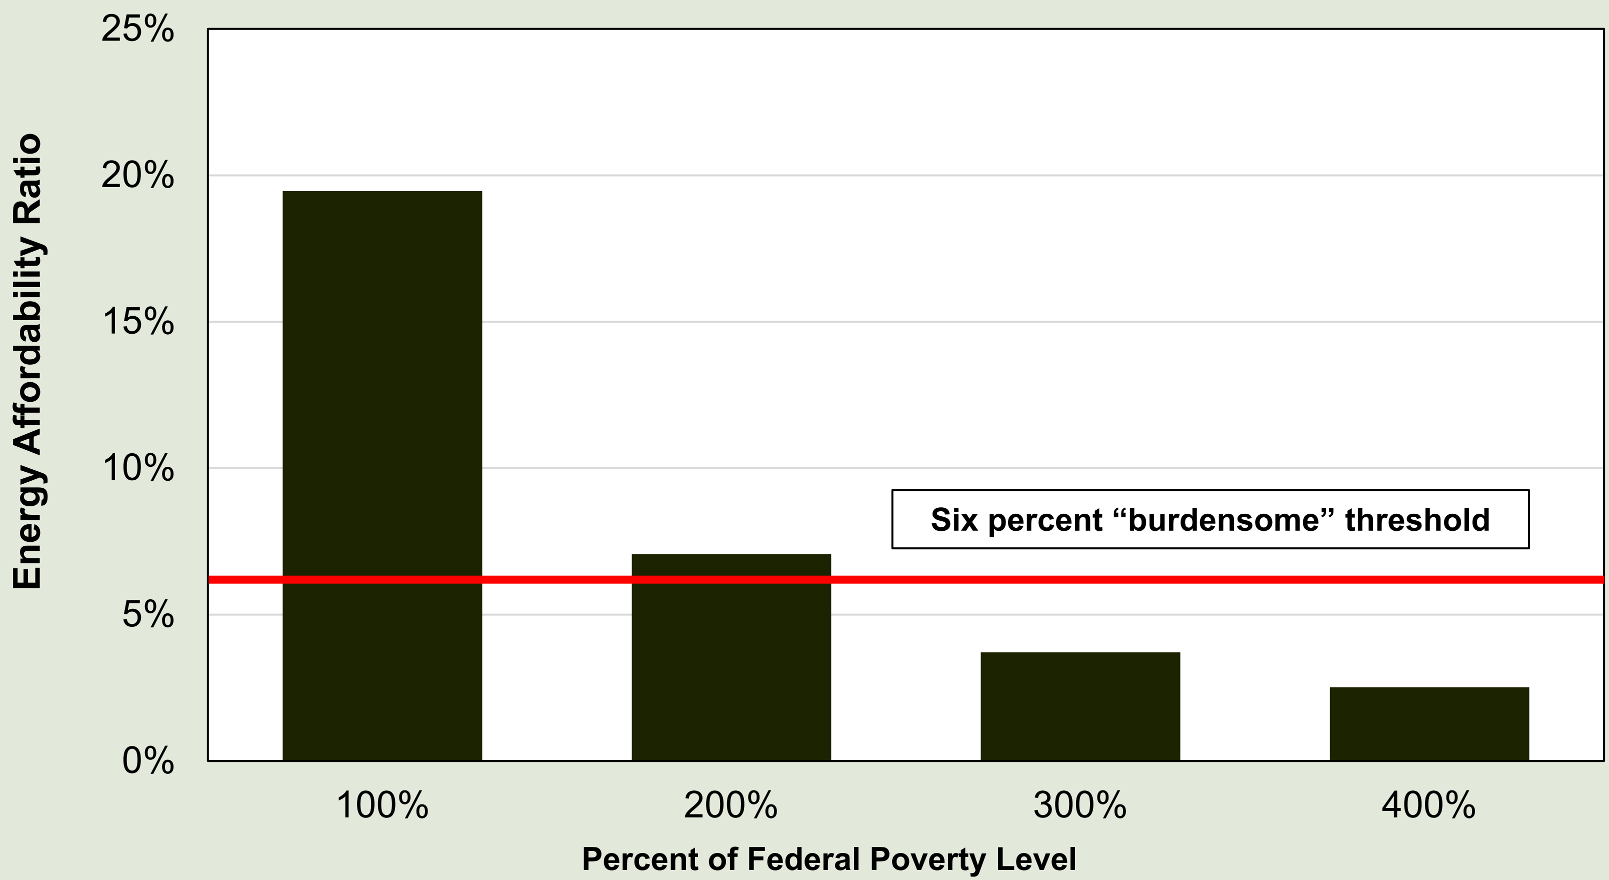
  Electric and Natural Gas Consumption: Average annual consumption by income level based on the EIA Residential Consumption Survey 2020.

  Electric and Natural Gas Rates: Based on PEPCO and Washington Gas and Light Tariffs.

Sources: American Community Survey 5-Year Estimates, 2015-2021. The Brattle Group, Pepco DC Conditional Demand Analysis, December 2017, EIA Residential Consumption Survey 2020.

D.C. energy affordability ratio by FPL, 2022

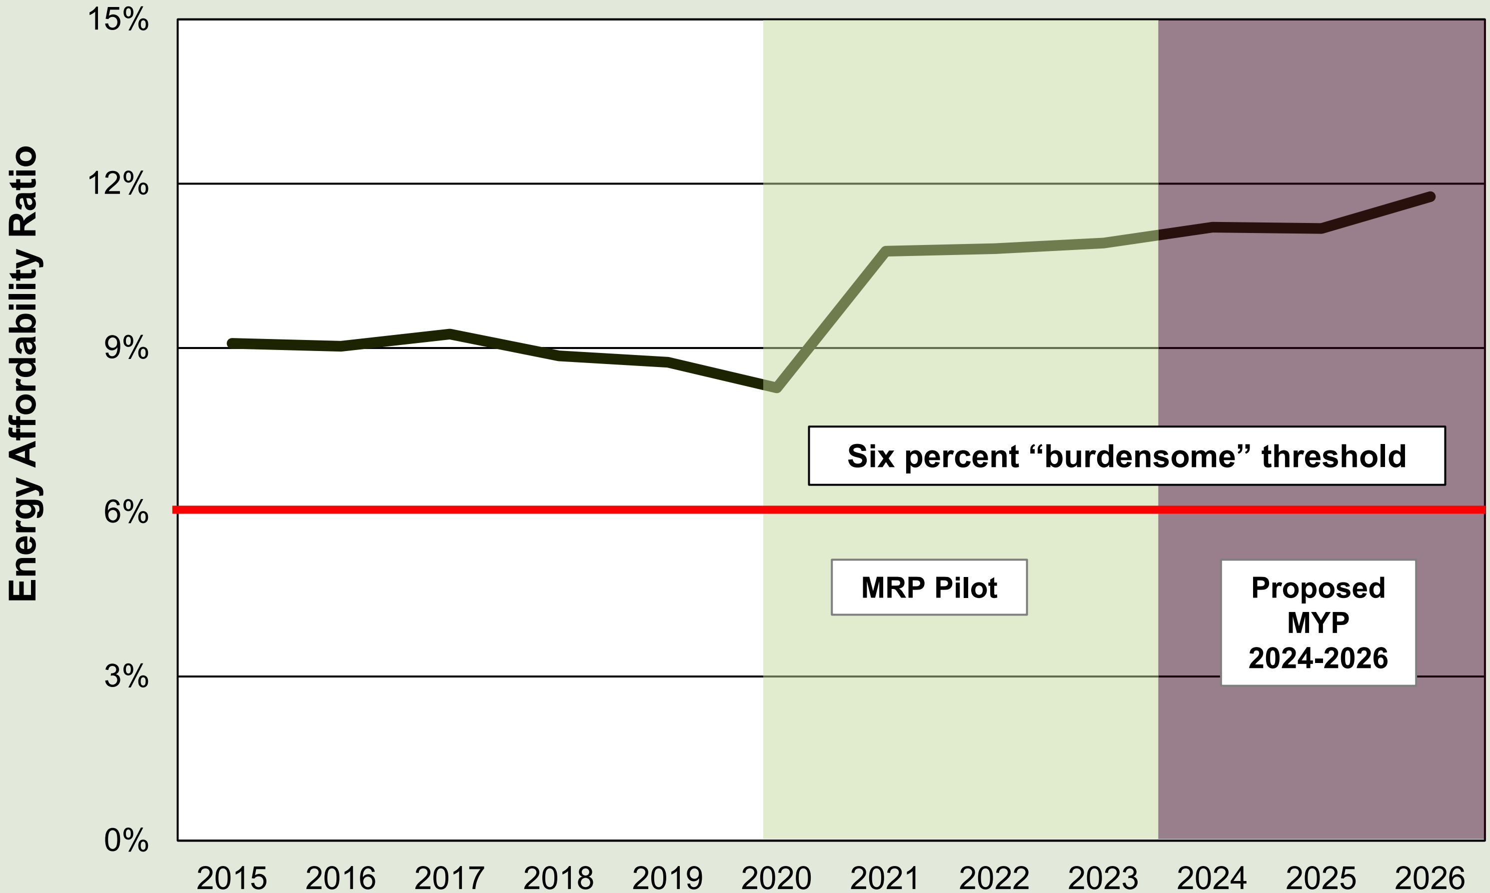
DC residents at 100 and 200 percent of the FPL exceed the burdensome threshold levels. Importantly, this analysis is limited to only electric and natural gas utility rates, and excludes utility rates associated with water, sewer, or telecommunications service. Therefore, this six percent threshold is likely conservative.



Source: ACS Community Survey 5-Year Estimates, Federal Poverty Level Guidelines 2022, DC Health Matters Average Household Size.

District energy affordability ratio: 15th percentile income

The lowest percentile is receiving the most harm from continued Pepco rate increases – **energy affordability ratios will rise to 11.8 percent by 2026.**

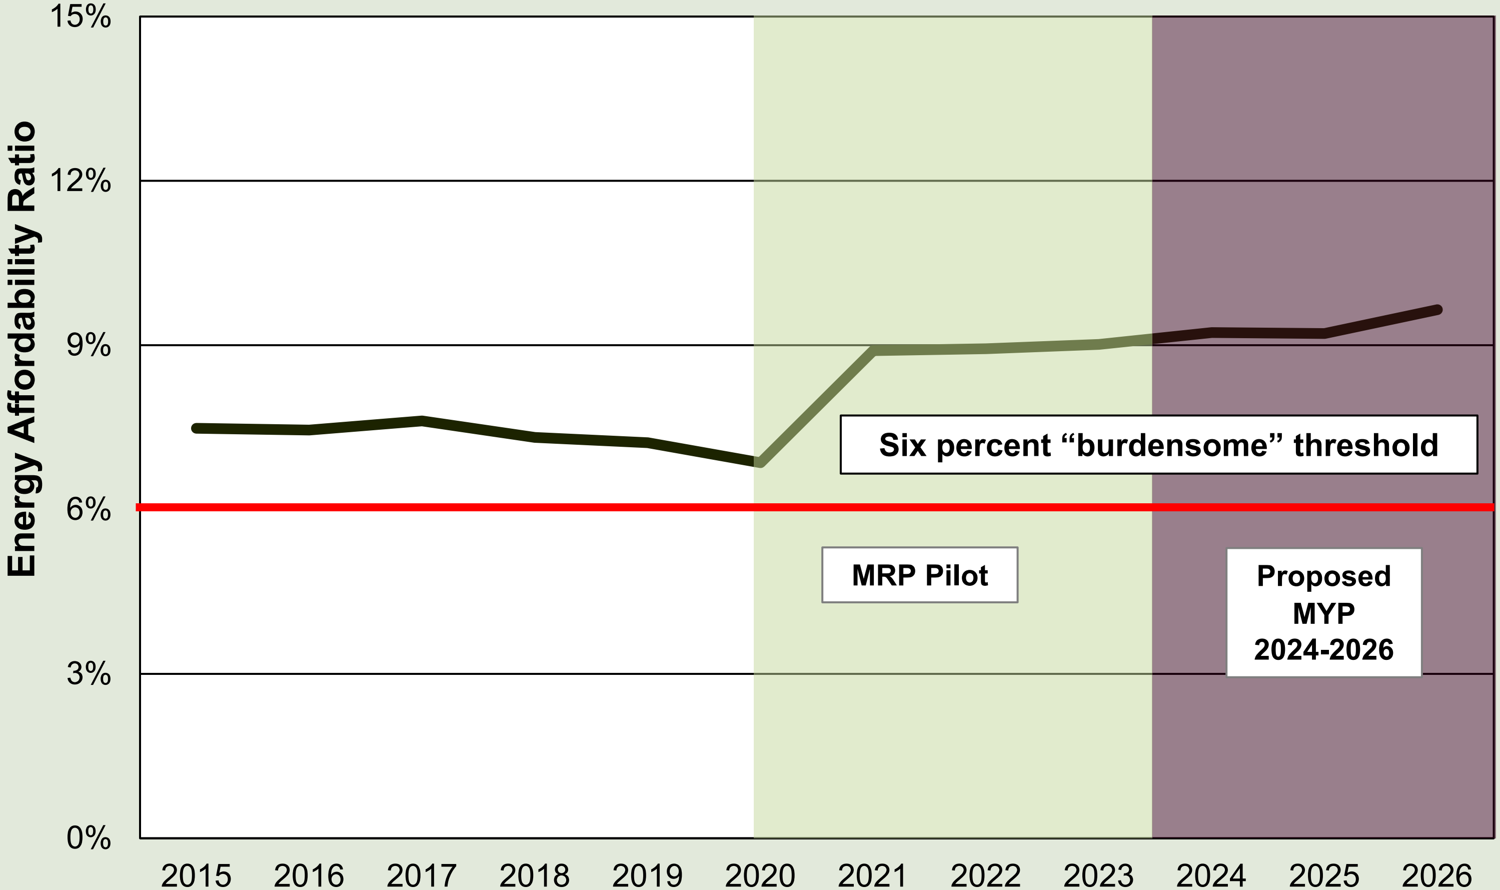


Source: Author's estimates from data provided in American Community Survey 5-Year Estimates 2015-2021, PEPCO Tariffs, FC 1176 OPC DR 3-19 and PEPCO (E)-5.

Exhibit OPC (A)-2
Formal Case No. 1176
David E. Dismukes, Ph.D.
Page 23 of 39

District energy affordability ratio: 15th percentile income with RAD discount

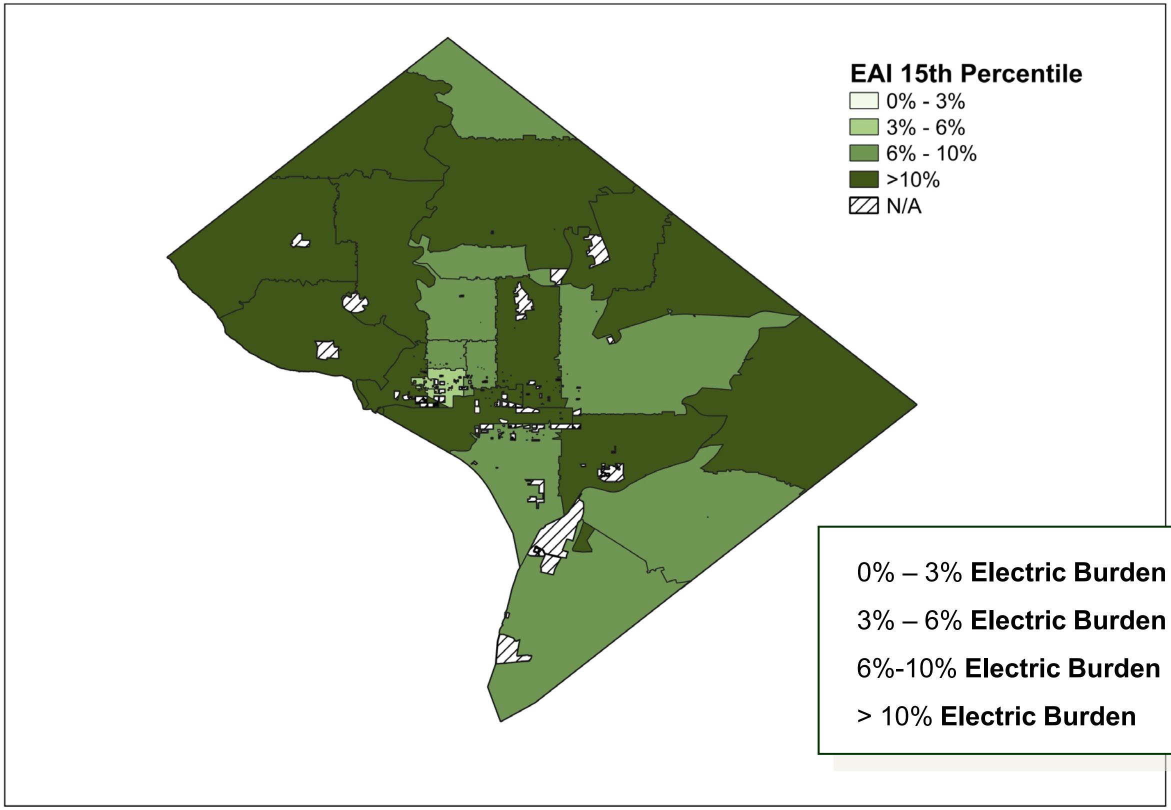
The RAD program offers eligible low-income customers a **25 percent discount** on their monthly electric bill. Even with RAD discounts, rates for the lowest 15th percentile of District ratepayers are **above burdensome levels** throughout the proposed MYP.



Source: Author's estimates from data provided in American Community Survey 5-Year Estimates 2015-2021, PEPCO Tariffs, FC 1176 OPC DR 3-19 and PEPCO (E)-5.

Affordability by location, lowest 15th household income percentile (2022)

The darker areas of the map shows that households in the lowest income quartile in the District **are all facing high or severe electric burdens**. Importantly, this analysis is limited to only electric utility rates in the District and excludes other utility rate burdens, including natural gas utility rates included in the previous analysis.



0% – 3% **Electric Burden**

3% – 6% **Electric Burden**

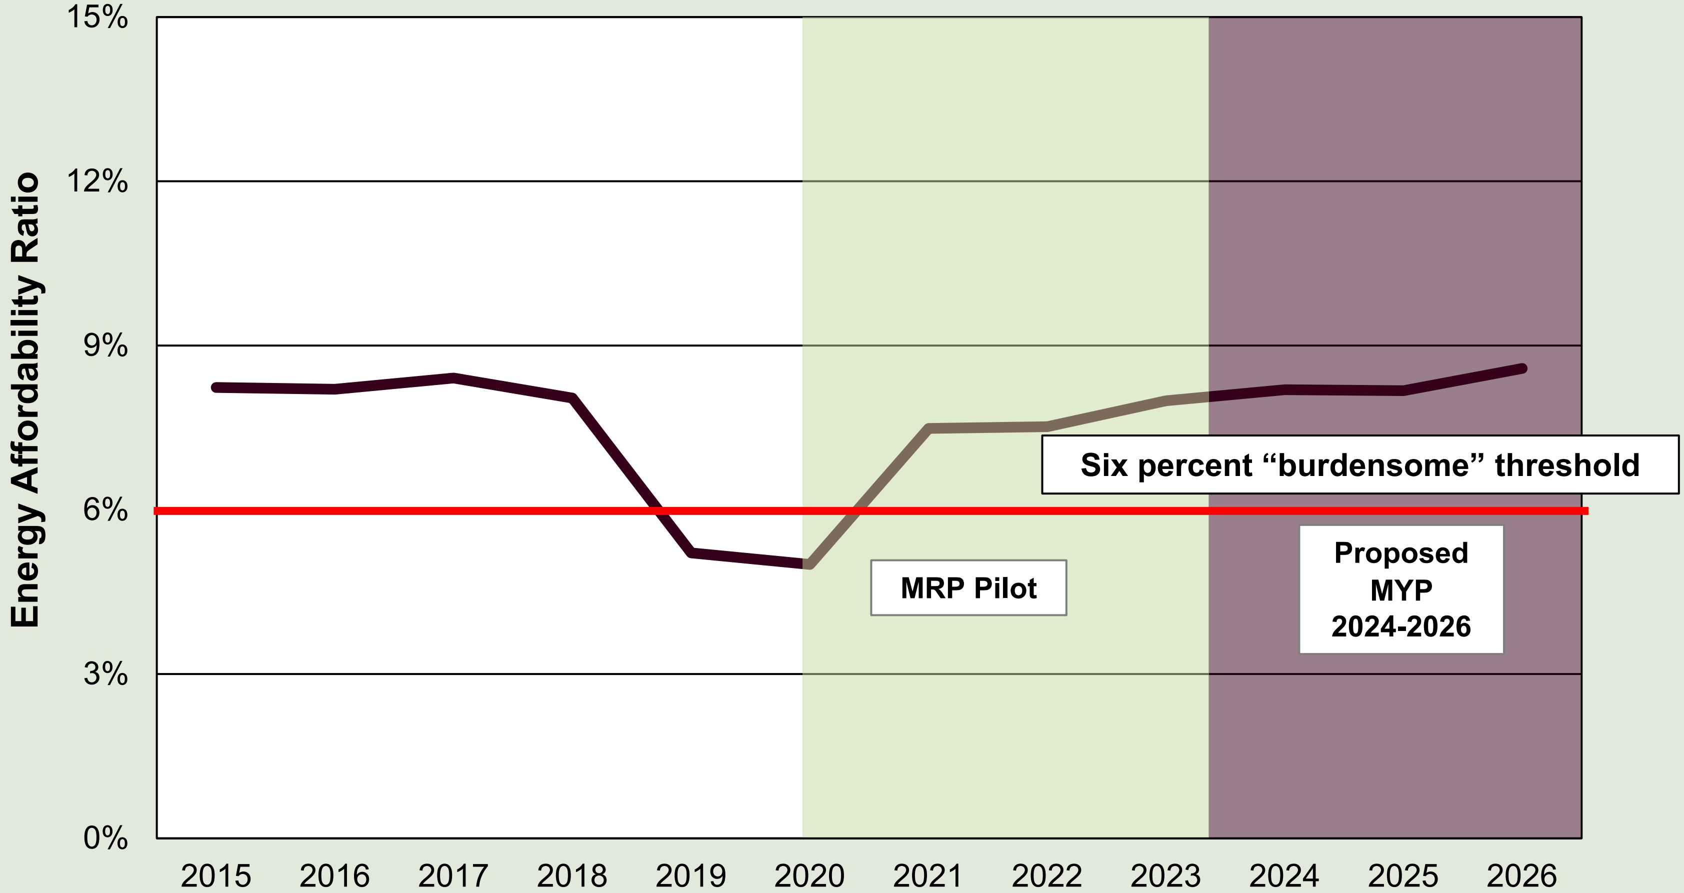
6%-10% **Electric Burden**

> 10% **Electric Burden**

Note: This affordability analysis utilizes average usage and expenditures provided by Pepco.
Source: FC 1176 OPC DR 3-47, ACS 2022 1-Year Estimates,

District energy affordability ratio: 20th percentile income

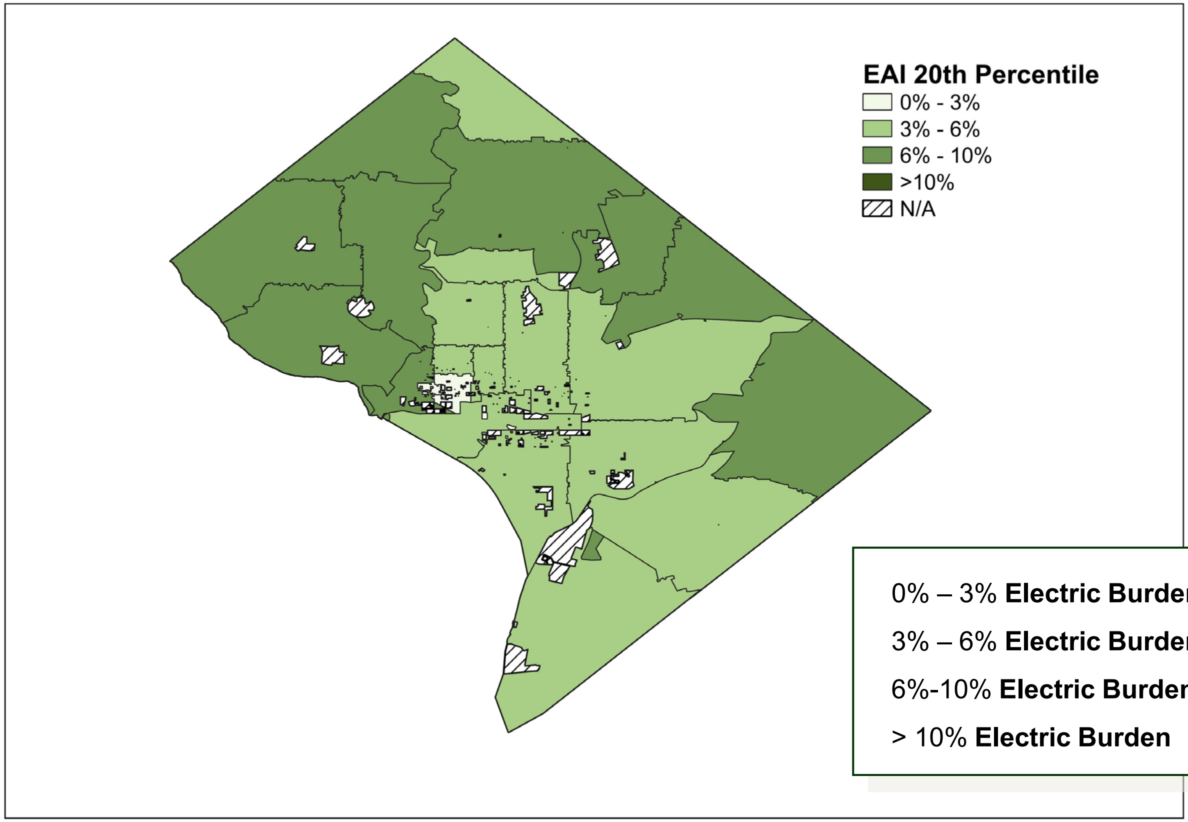
The energy affordability for District residents at the 20th percentile has seen high levels of energy burden since at least 2015. **This is estimated to grow during the proposed MYP.**



Source: Author's estimates from data provided in American Community Survey 5-Year Estimates 2015-2021, PEPCO Tariffs, FC 1176 OPC DR 3-19 and PEPCO (E)-5.

Affordability by location, lowest 20th household income percentile (2022)

Households in the 20th lowest household income quartile **are all facing high to moderate electric burdens.** Importantly, this analysis is limited to only electric utility rates in the District, and excludes other utility rate burdens, including natural gas utility rates included in the previous analysis.



0% – 3% **Electric Burden**

3% – 6% **Electric Burden**

6%-10% **Electric Burden**

> 10% **Electric Burden**

Note: This affordability analysis utilizes average usage and expenditures provided by Pepco.
Source: FC 1176 OPC DR 3-47, ACS 2022 1-Year Estimates,

Alternative energy affordability measures: Hours at Minimum Wage

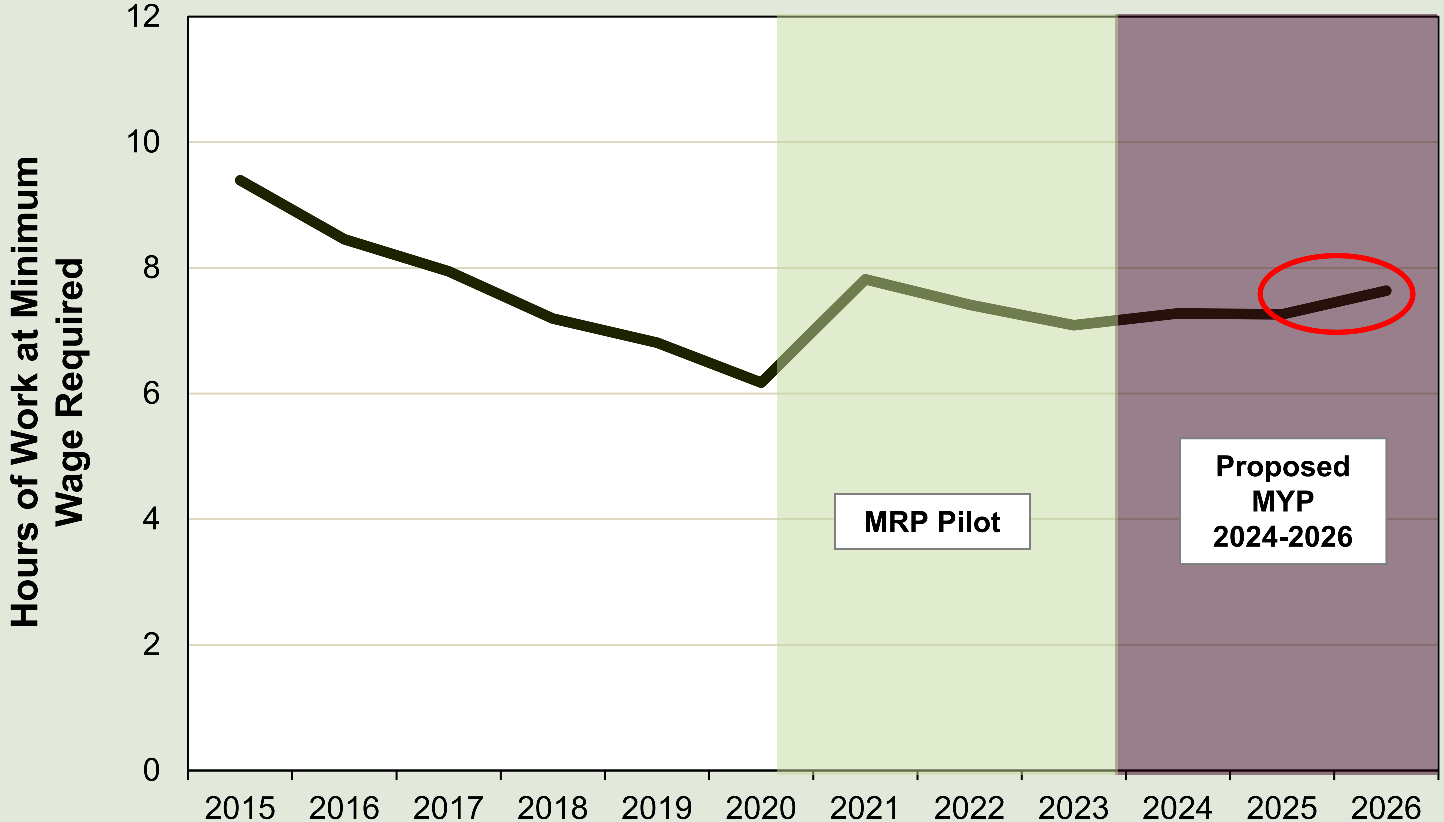
- The hours at minimum wage (HM) measures **the number of hours of earned employment at the minimum wage necessary for a household to pay for essential services: in this case, electricity and natural gas.**
- **Hours at minimum wage** = electric and natural gas bills / minimum wage.
- Electric and natural gas rates were based on 15th percentile income consumption.
- This metric quantifies the number of hours low-income residents must work to meet their basic electricity and natural gas expenses.

ACADIAN CONSULTING GROUP

Affordability Analysis

Hours at minimum wage (HM)

The number of hours needed to pay for electric and natural gas bills has increased and will **continue to increase with the proposed MYP despite minimum wages increasing by 62 percent since 2015.**



A DC resident will have to work close to 7.64 hours per week at minimum wage to pay their electric and natural gas bills if the MYP is approved.

Source: Author's estimates from data provided in American Community Survey 5-Year Estimates 2015-2021, PEPCO Tariffs, FC 1176 OPC DR 3-19 , PEPCO (E)-5, and DC Historic Minimum Wage https://fred.stlouisfed.org/series/STTMINWGDC.

Pepco Low-Income Affordability Programs

ACADIAN CONSULTING GROUP

Pepco Existing Programs

Affordability Assistance Programs in D.C.

Residential Aid Discount Program (RAD): provides eligible customers a discount of about 25 percent on their monthly electric bill.

Utility Discount Programs (UDP): provides eligible low-income customers up to $475 per year on electric bills, $276 during the winter season on gas bills, and over $962 per year on water and sewer bills.

Weatherization Assistance Program (WAP): provides income eligible households with energy audits and installation of audit-recommended energy efficiency measures and water conversation to promote energy efficiency.

Solar for All: offers incentives to low to moderate income households for solar panel installations. According to the program, eligible households can expect to see a 50 percent savings on their electric bill over 15 years.

Low Income Home Energy Assistance Program (LIHEAP): assists income-eligible households with cooling and energy costs through a $250-$1,800 one-time benefit.

Conclusions & Recommendations

Conclusions and Recommendations

ACG makes the following recommendations:

- **Do not approve the proposed MYP**. The current MRP Pilot has done nothing but make electricity more expensive in the District.
- **Limit Pepco's proposed annual capital expenditures** to levels that are more sustainable and consistent with affordability concerns.
- Require Pepco to **regularly examine and file affordability analyses**.
- **Review the Pepco's low-income proposals** for:

  (a) potential modifications that **expand coverage** to a larger number of eligible households and

  (b) **means test and scale financial assistance levels** to assure adequacy, minimize adverse rate impacts on other supporting customers, and to get the "biggest bang for the buck" in low-income assistance.

ACADIAN
CONSULTING GROUP

The implications of alternative regulation for retail ratepayers in the District of Columbia.

Prepared on the behalf of the District of Columbia, Office of Peoples Counsel

David E. Dismukes, Ph.D.
Acadian Consulting Group

January 12, 2024

Table of Contents

Executive Summary – Overall Findings

There are **three major forms of alternative regulation**: Formula Rate Plans ("FRPs"); Performance-Based Ratemaking ("PBR") plans; and Multi-Year Rate Plans ("MYRPs"). To date, **none have led to any meaningful nor measurable ratepayer benefits.** Alternative regulation **has not resulted in any sustainable nor distinctly measurable improvement in reliability or quality of service.**

Alternative regulation mechanisms have resulted in large rate increases with very few rate decreases nor earning sharing opportunities.

In addition, **no measurable operating costs efficiencies have arisen in any state due to alternative regulation**. In fact, most states **have seen a deterioration in capital investment discipline and huge gains in rate base due to alternative regulation**.

There is <u>not one single state adopting alternative regulation that has shown outcomes that can be held out as an unequivocal "success" for ratepayers.</u>

Study purpose

The Acadian Consulting Group, LLC ("ACG") has been asked by the District of Columbia ("District"), Office of the Peoples Counsel ("OPC") to **examine alternative regulation**.

The purpose of this analysis is to assess and evaluate the potential of alternative forms of regulations. This analysis reviews the potential benefits, or lack thereof, of alternative regulation as it has been implemented throughout the United States and is intended to complement OPC's case-in-chief which will directly address Pepco's proposed extension of the MYRP.

The analysis finds that few to no ratepayer benefits will arise from the adoption of alternative regulation and will likely lead to excessive capital investment and higher electricity rates. Alternative regulation **has not led to any meaningful nor measurable operating cost efficiencies nor has it resulted in any improvements in reliability or quality of service.**

Section 2: The fallacies of alternative regulation

Why alternative regulation?

Moral hazard notes that often, the **informational asymmetry** between regulators and regulated companies, **prevents traditional regulation from forcing the most optimal outcome**.

The **basis for alternative regulation is that while optimal costs are difficult to observe, profits are not**. Thus, alternative regulation seeks to **eliminate the traditional base rate case regulatory process** to one where rates are automatically increased by a formula or some fixed allowed levels. **This pricing "flexibility," supposedly, gives utilities greater incentives, through higher profits, to seek capital and operating cost efficiencies.**

The entire basis for alternative regulation is that **unobservable efficiency opportunities** actually **exist** and the **benefits** of changing the current form of regulation are **greater than the costs**.

<u>**However, actual experience has not proven either premise is true, nor has alternative regulation been successful at: (a) lowering rates; (b) generating cost/operating efficiencies; (c) improving service quality or reliability; and (d) creating ratepayer benefits**</u>**.**

How does traditional regulation differ from alternative regulation?

Alternative regulation starts with a large policy leap of faith: regulators have to be willing to allow **prices (or revenues)** become **"decoupled"** with **traditional (utility-specific) measures of costs**.

Such approaches **challenge the traditional policy and legal foundations of utility regulation** that set rates on **"known and measurable"** information to assure those rates are **fair, just, and reasonable**.

Alternative regulation **presumes that if utilities are given pricing and investment flexibility, they will lead to considerable efficiencies** that can be **shared with ratepayers** in the form of (a) l**ower retail rates and (b) earnings or profit sharing.**

However, **alternative regulation shifts all utility performance risk onto ratepayers**: utilities are allowed, up front, to increase rates to increase or preserve profitability. Benefits only arise if utilities create operating and capital efficiencies – **if these efficiencies do not arise, ratepayers receive no benefits from alternative regulation and thus bear the risk of the poor utility performance**.

Does alternative regulation lead to ratepayer benefits?

To date, there is **no systematic evidence that clearly shows that alternative regulation, for electric utilities, has resulted in any (a) reduced/improved retail rates; (b) improved cost efficiencies; or (c) improved quality of service or reliability.**

In fact, the **evidence to date shows that various different forms of alternative regulation have resulted in the opposite**: (a) increased rates; (b) increased inefficiencies, particularly capital investment inefficiencies; (c) little to no improvement in reliability or quality of service.

Very little, **to zero, ratepayer financial benefits have arisen from "sharing" or "earnings sharing mechanisms"** as applied to most major forms of alternative regulation (i.e., FRPs, PBRs, MYRPs).

In fact, **many states** that have utilized alternative regulation mechanisms in the past, **have abandoned their use**. For instance, **Maine and Vermont do not use PBR mechanisms** anymore, and **North Dakota, Indiana, Colorado, and Oklahoma no longer use MYRPs.**

Reduced administrative/regulatory costs?

To date, there is **no systematic evidence that clearly shows that alternative regulation results in lower regulatory or administrative costs.**

Most utilities that are under some form of alternative regulation continue to make repeated and regular regulatory filings. **It is a myth that alternative regulation significantly reduces administrative and regulatory costs**.

Further, rate proceedings such as FRPs and MYRPs **have compliance and or reconciliation proceedings** that continue to require regulatory and administrative costs. It has not been shown that **the sum of these smaller and repeated annual filings offset base rate expenses** incurred prior to the alternative regulatory regime.

Lastly, future rate case filings can also be more contentious and require additional resources since the prudence of many cumulative capital investments are evaluated at that time.

Alternative Regulation Fallacies

The theoretic basis for alternative regulation is flawed.

The **theoretic literature supporting alternative regulation** was written and developed with the **experience of the 1980s-1990s in mind**. This period followed a **large era of major capital/capacity expansion**, particularly in the development of nuclear and coal fired electric generation.

Capital and capacity utilization during the 1980s-1990s was abysmal. Consider that throughout the 1980s, **nuclear generators operated at an average utilization of between 40 to 60 percent**. **Coal plant utilization**, particularly for super-critical units, were equally low.

In addition, **energy utilities (electric and natural gas) were also saddled with out-of-market longer-term generation contracts**, executed during a period in which price/cost inflation was expected to increase at a double digit percents and when fossil fuels, particularly natural gas, were expected to be in short supply.

This **high degree of industry inefficiency upon which alternative regulation is based simply does not exist today nor do the technical potentials for achieving better overall cost and pricing efficiencies**.

Why is alternative regulation no longer appropriate/relevant?

Today's utility investments **are intended to address a wide range of market failures and social policy goals**, not generate cost efficiencies including:

- Renewables (GHG externalities)
- Safety/reliability (GHG externalities, public goods)
- Environmental (GHG externalities)
- Energy efficiency (GHG, externalities, imperfect info, risk/uncertainty)

The regulatory challenge is that these policies' benefits, by definition, **do not have an easily-measured market value**. Just about **any benefit estimate can be used to justify any level of the investment**. This runs counter to the goals of alternative regulation to create efficiencies.

Further, <u>**few of these social/environmental investments will lead to improved system efficiency**</u> since many are non-revenue generating or have no/little capacity value, resulting in lower system utilization, <u>**thus, making alternative regulation irrelevant and useless.**</u>

Regulation and the capital investment bias

Since the 1960s, the **theory and practice of utility regulation has recognized that utilities have a capital investment bias**. This bias is technically referred to as the **"Averch-Johnson effect"** after the two economists publishing the theory in the *American Economic Review* – but is more **commonly referred to as "gold plating"** in utility practice.

This **capital investment bias notes that the larger a utility's investment base, the larger the potential earnings**. The larger and faster this investment base (or "rate base") grows, the faster the potential earnings growth.

Historically, **utilities have justified very large capital/capacity investments on energy usage growth** that, while slowing, has still been considerable over the past three decades.

Over the past decade, however, utilities have faced slowing to potentially contracting energy usage. **No usage growth means no need for capacity, no capacity needs mean no capital investment, and no capital investment means lower earnings opportunities**.

How do utilities grow earnings in a low to non-growth environment?

Utilities are finding new alternatives to **grow their rate base** through **social investments** that include those **dedicated to reliability/resiliency, safety/security, renewables, energy storage, and other emerging new technologies and resources.**

The **basis for these investments contradicts the purposes of alternative regulation**. First, social investments are often uneconomic. This means that **alternative regulation can not incent utilities into making cost-effective decisions since the resources themselves are not cost effective**.

Second, **social investments do not lead to improved system efficiencies** and can lead to lower, not higher system utilization **running counter to the purpose of using alternative regulation**.

Third, **alternative regulation delegates social investment prioritization to for-profit utilities and their shareholders**. This outcome contradicts traditional regulation that allows utilities, under the direct supervision of regulators, to make these investments if the gains are shared with ratepayers.

Media recognition of the new utility capital bias.

Even the **media recognizes this capital bias** in the face of flat electricity demand growth – **a trend that is proven to be exacerbated with alternative regulation**.

Utilities' Profit Recipe: Spend More

To expand regulator-imposed earnings caps, electricity producers splurge on new equipment, boosting customers' bills

Every time Southern California Edison replaces a 50-year-old pole with a new one, it has a fresh investment on which it is eligible to earn an annual profit. *PHOTO: FRED PROUSER/REUTERS*

By REBECCA SMITH

April 20, 2015 6:04 p.m. ET

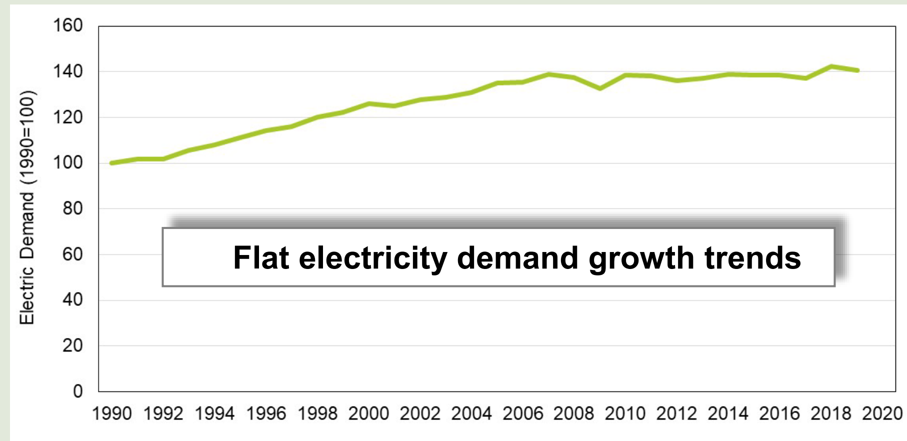
101 COMMENTS

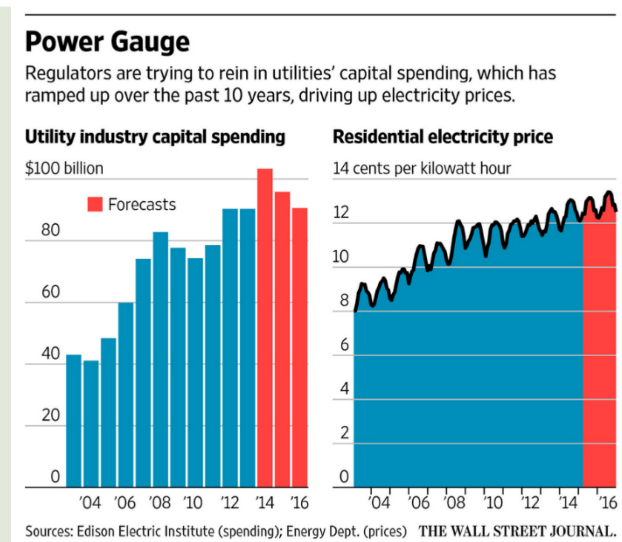
Families in New York are paying 40% more for electricity than they were a decade ago. Meanwhile, the cost of the main fuel used to generate electricity in the state—natural gas—has plunged 39%.

Why haven't consumers felt the benefit of falling natural-gas prices, especially since fuel accounts for at least a quarter of a typical electric bill?

One big reason: utilities' heavy capital spending. New York power companies poured $17 billion into new equipment—from power plants to pollution-control devices—in the past decade, a spending surge that customers have paid for.

New York utilities' spending plans could push electricity prices up an additional 63% in the next decade, said Richard Kauffman, the former chairman of Levi Strauss & Co. who became New York's energy czar in 2013. It's "not a sustainable path for New York," he said.





Major forms of alternative regulation: multiyear rate plans ("MYRPs").

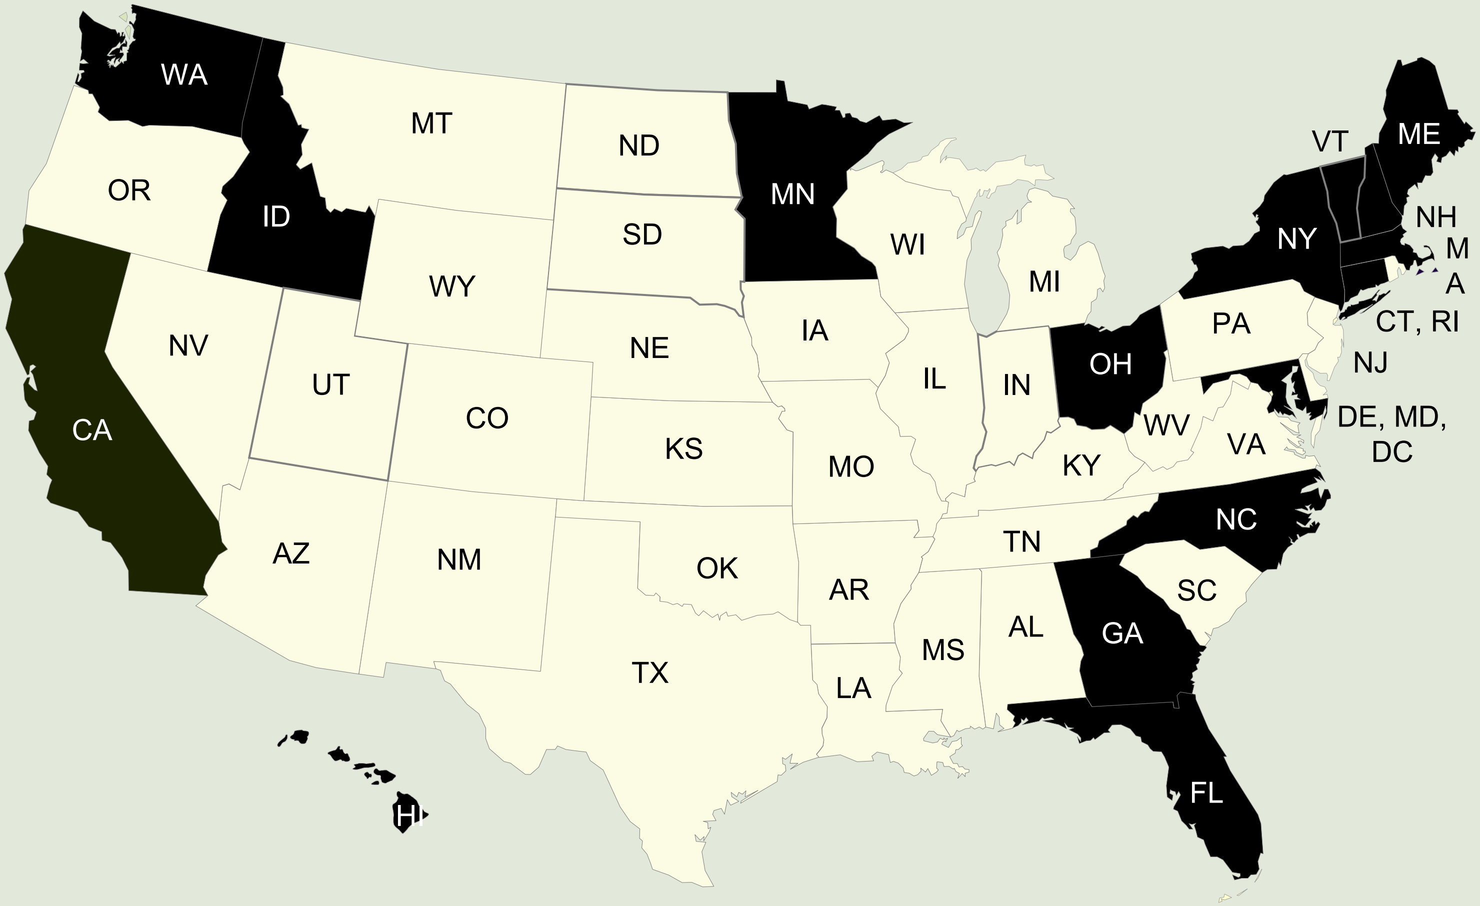
Multi-Year Rate Plans ("MYRPs") are rate plans **designed to span multiple years similar to PBR.**

However, unlike PBR, **MYRPs do not rely on a formula to determine future rate increases and instead are approved with defined rate increases each year of the proposed plan**. Due to this, MYRPs tend to be shorter in duration, typically only two or three years in total.

The **biggest concern with MYRPs is the approval of large upfront rate increases that are based on projected, not actual information.** Additionally, depending on the extent of these allowed future rate increases, **MYRPs may include little to no incentive for the utility to control costs during the term of the plan. Once rates have been allowed to increase, it is difficult to "claw back" those increases in the form of expense/investment disallowances.**

Prevalence of MYRPs.

MYRPs are used in several states in the east, **primarily in states New England states.**



Sources: Electricity Regulation for a Customer-Centric Future – Survey of Alternative Regulatory Mechanisms, Guidehouse (for EEI), 2Q 2020; Idaho PUC Case No. AVU-E-23-01, AVU-G-23-01; DC PSC FC 1156; MD PSC Case No. 9655; VT PUC Case No. 18-1633-PET; NC PUC Docket No. E-2, SUB 1300, S&P Global RRA Regulatory Focus.

Major forms of alternative regulation: formula rate plans ("FRPs").

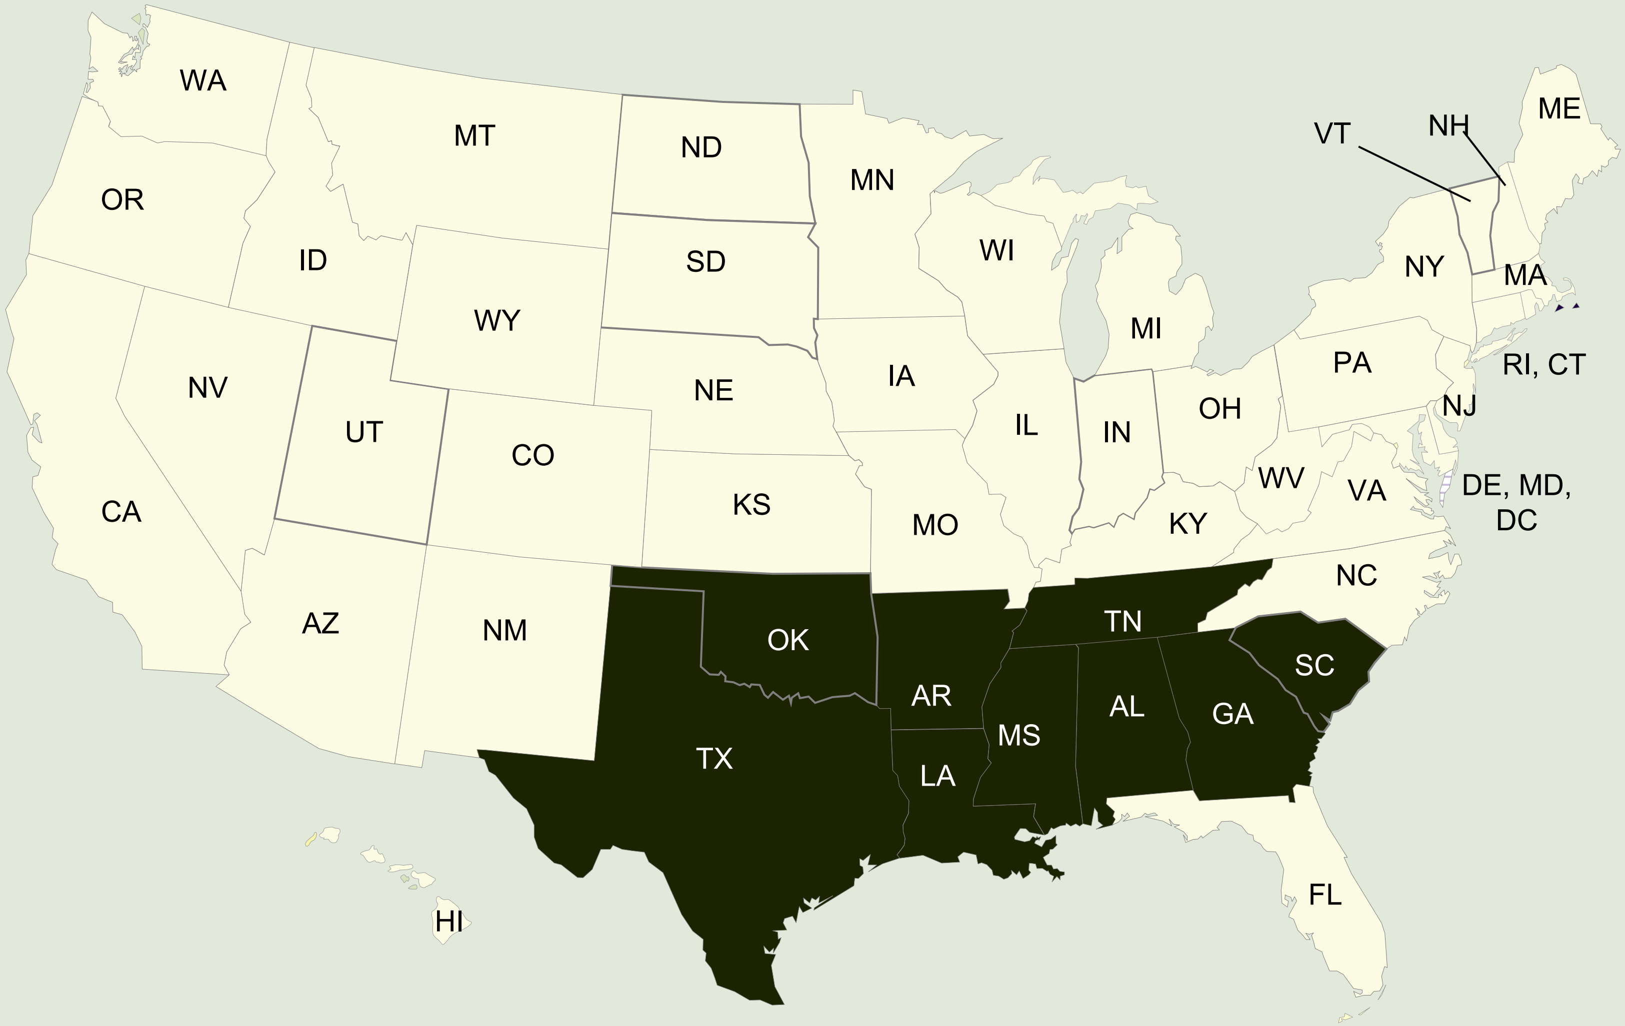
Formula rate plans ("FRPs") are a form of alternative regulation **that allows for annual rate adjustments between rate cases based on the difference between a utility's achieved return on equity to an established target return on equity set during the prior rate case**. Essentially FRPs **allow for annual "mini rate cases"** that involve a review of utility expenditures, capital investments, and revenue variances (**challenging the claim of "lower regulatory and administrative costs"**).

FRPs in practice, however, **have been plagued by constant rate increases to fund growing utility investments, inefficient utility capital investments, and in some cases utility windfall profits due to outdated capital market assumptions.**

FRPs also **have been criticized for reducing the ability of independent oversight of utility expenses and capital investments** since annual FRP reviews are typically conducted on a significantly expedited compared to traditional rate cases.

FRP use throughout the southeast.

FRPs are almost **exclusively used in the southeast**.



Source: "Innovative Rates, Non-Volumetric Rates, and Tracking Mechanisms: Current List" American Gas Association, 2016.

Major forms of alternative regulation: performance-based regulation ("PBRs").

Performance-Based Regulation ("PBR") allows either utility revenues or prices (i.e. rates) to increase each year using a set formula that **importantly includes an inflation term ("I") and a productivity offset ("X").** This "I-X" component is the core of such regulation paradigms and **represents a guaranteed rate increase**.

Revenue Cap

$$\overline{R}_t = (\overline{R}_{t-1} + CGA * \Delta Cust) * (1 + I - X) \pm Z$$

Price Cap

$$\overline{P}_{m,t} = \overline{P}_{m,t-1} * (1 + I - X) \pm Z$$

Where:

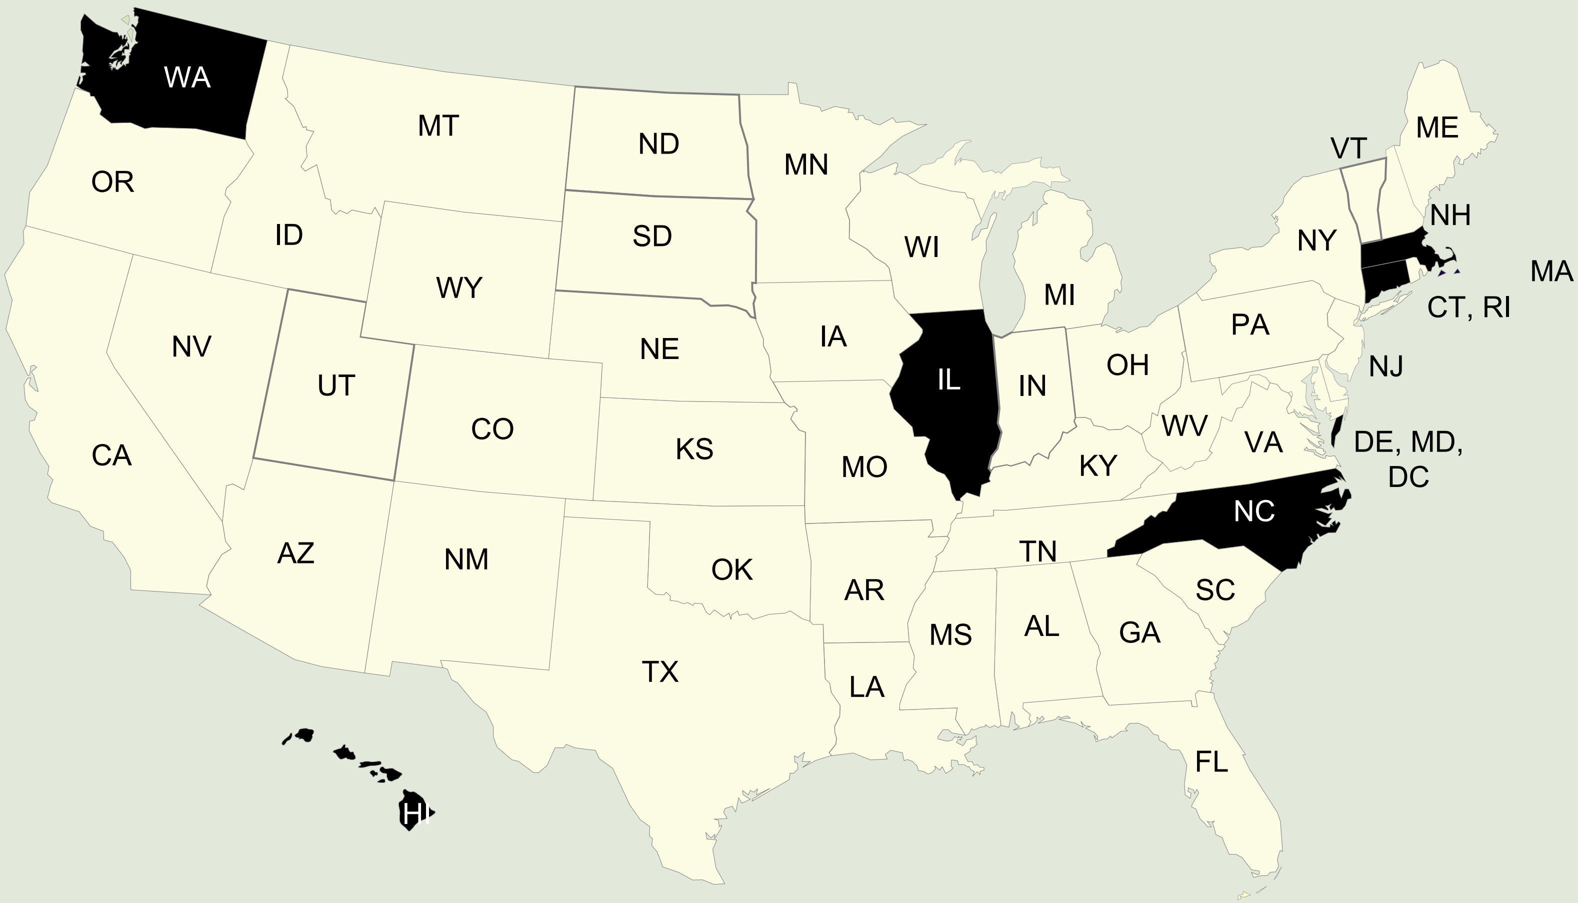
I = Annual percent change in prices (Inflation index)

X = An index of expected efficiency gains (Productivity offset)

Z = Adjustments for unforeseen events beyond management's control

Prevalence of electric utility PBR plans.

PBRs are rarely and sporadically used in a handful of states.



Note: CT and WA are in in the process of finalizing PBR rules, but most utilities use FRPs at the current time in WA.

Section 3: Alternative regulation increases rates

Alternative regulation increases rates.

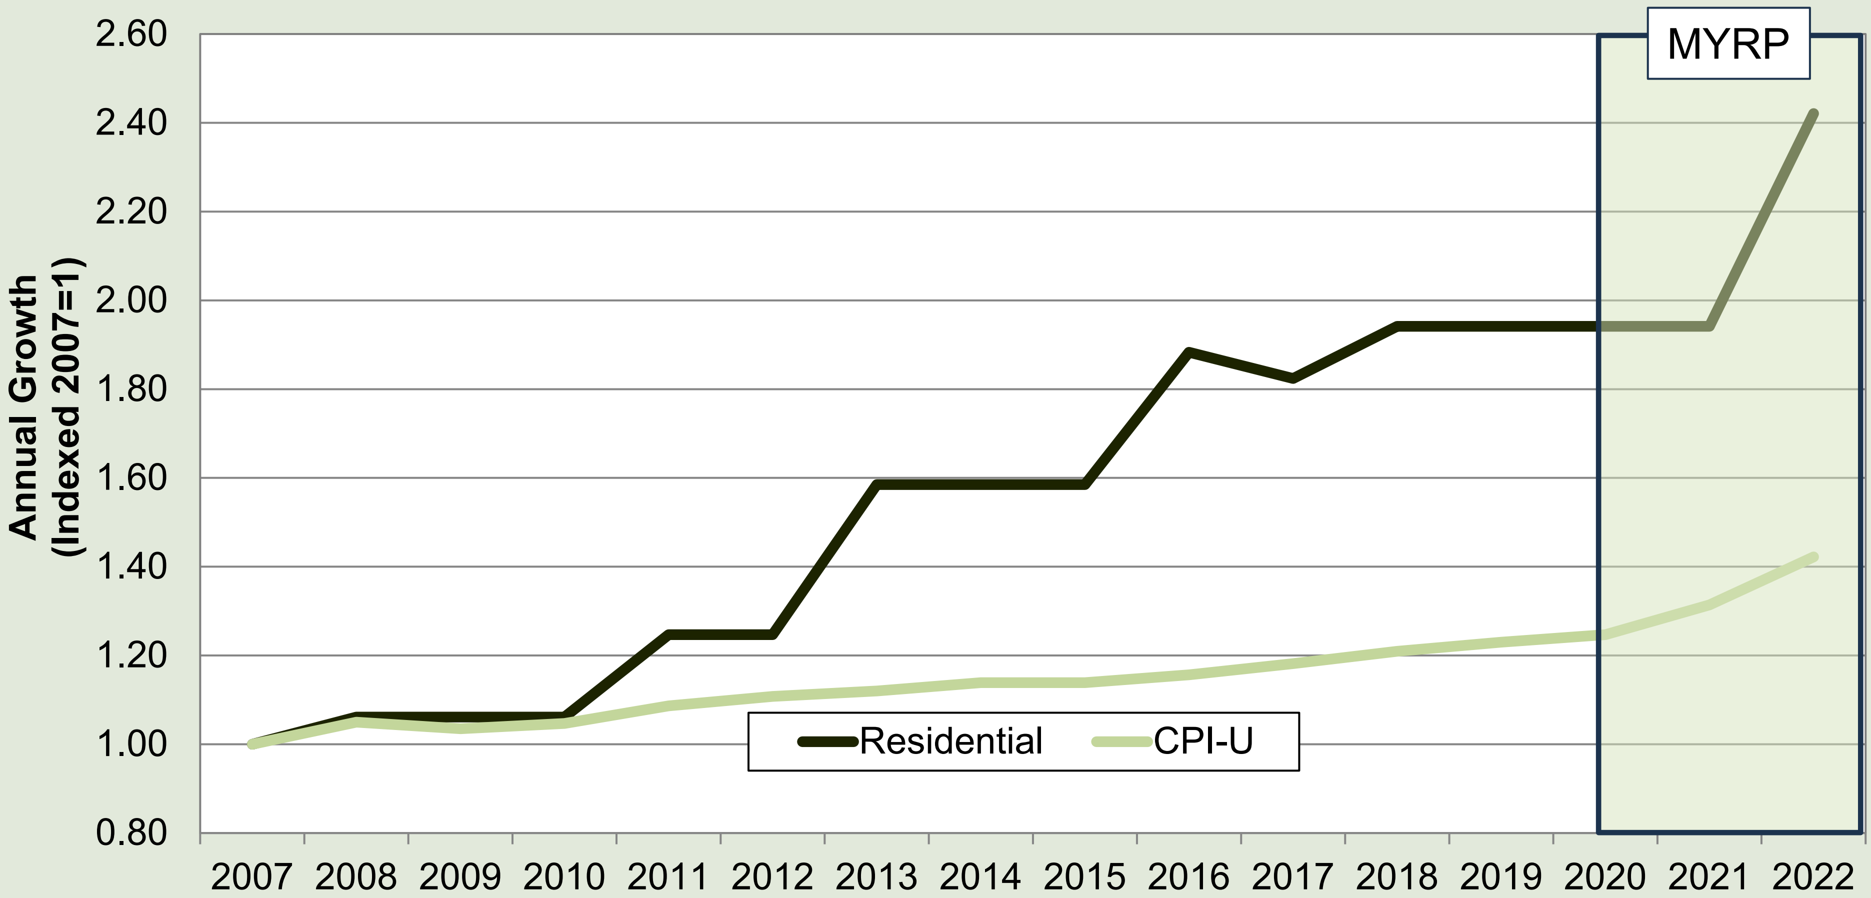
Alternative regulation does not lead to any meaningful nor measurable ratepayer benefits. Utilities that have been allowed to adopt various forms of alternative regulation (MYRPs, PBRs, FRPs) have **requested very large and generous rate increases, in most instances, orders of magnitude larger than what was historically requested under traditional regulation**.

There are simply **no "real-world" examples nor evidence that shows that ratepayers have received any meaningful benefits, particularly in the form of rate decreases, from alternative regulation.**

The following analysis provides several **real-world examples of post-alternative regulation rate increase requests**.

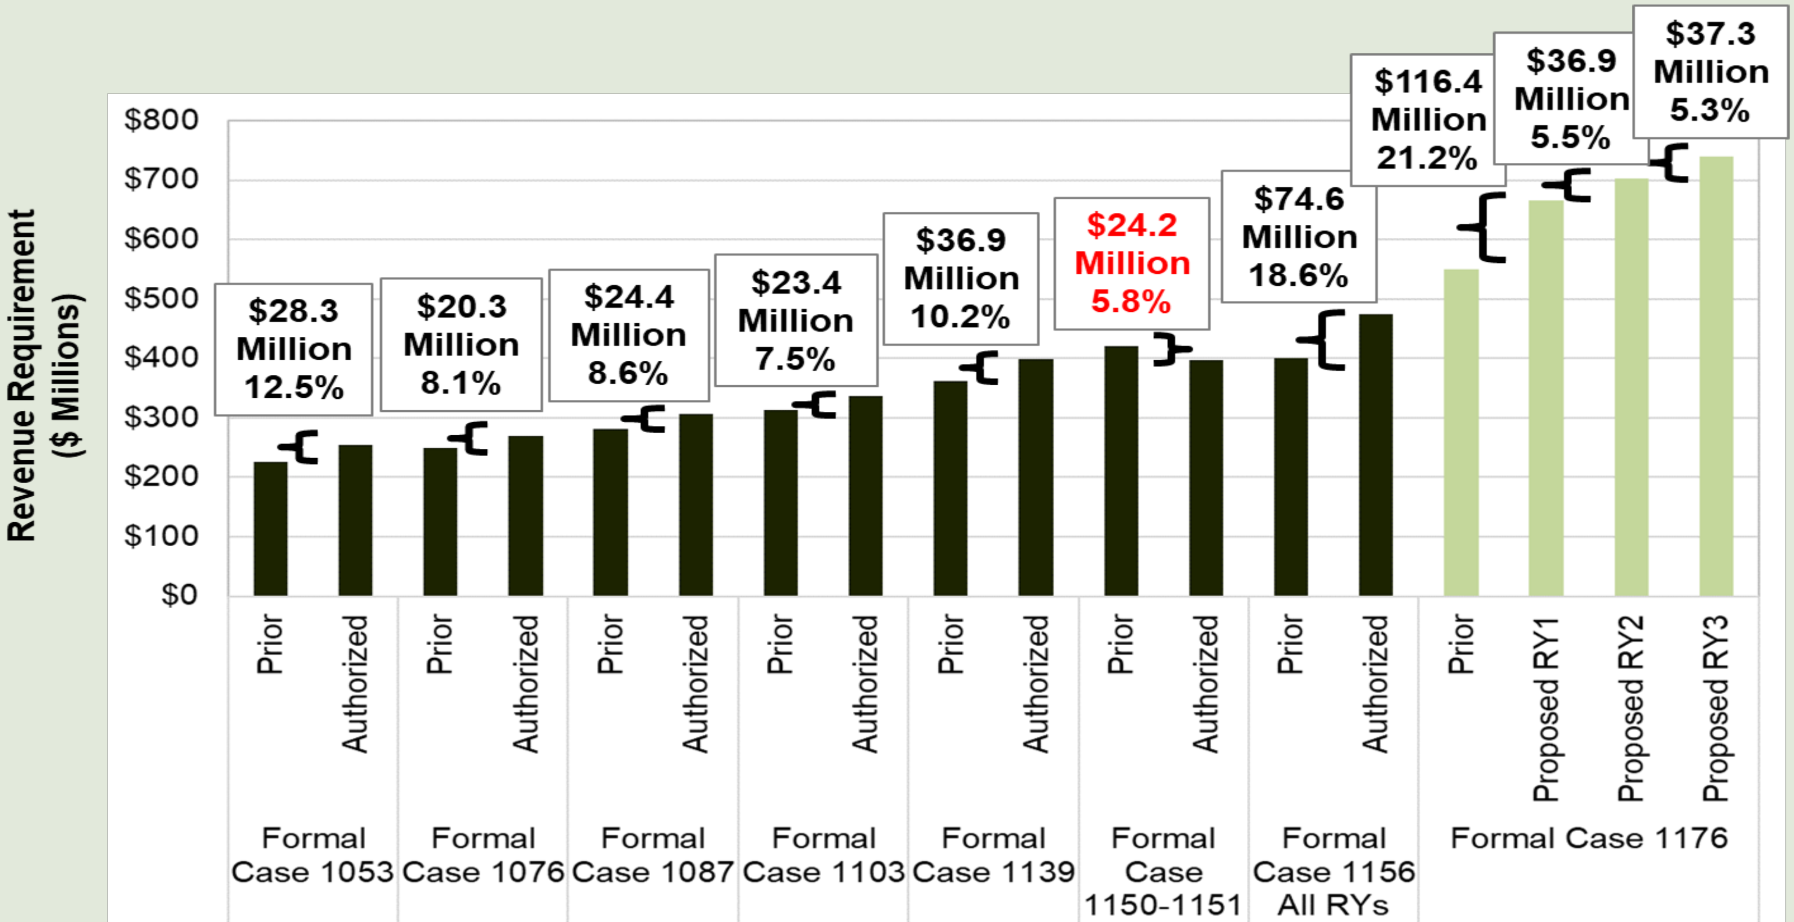
MYRP deficiency example: Pepco DC.

Even under traditional regulation, Pepco's rates were increasing faster than inflation. **Rate increases for all customers accelerated in a dramatic fashion after MYRP implementation**. Current pending MYRP is even greater than prior two years.



MYRP deficiency example: PEPCO DC.

Pepco's most recent MYRP filing requests an increase of $190.6 million over three years. This is equal to a **32 percent increase** in distribution rates, or nearly **10 percent per year of the proposal**.



MYRP deficiency example: Avista (Washington)

Under alternative regulation, Avista has imposed **annual rate increases that have exceeded 6 percent (almost $350 million since 2015).**

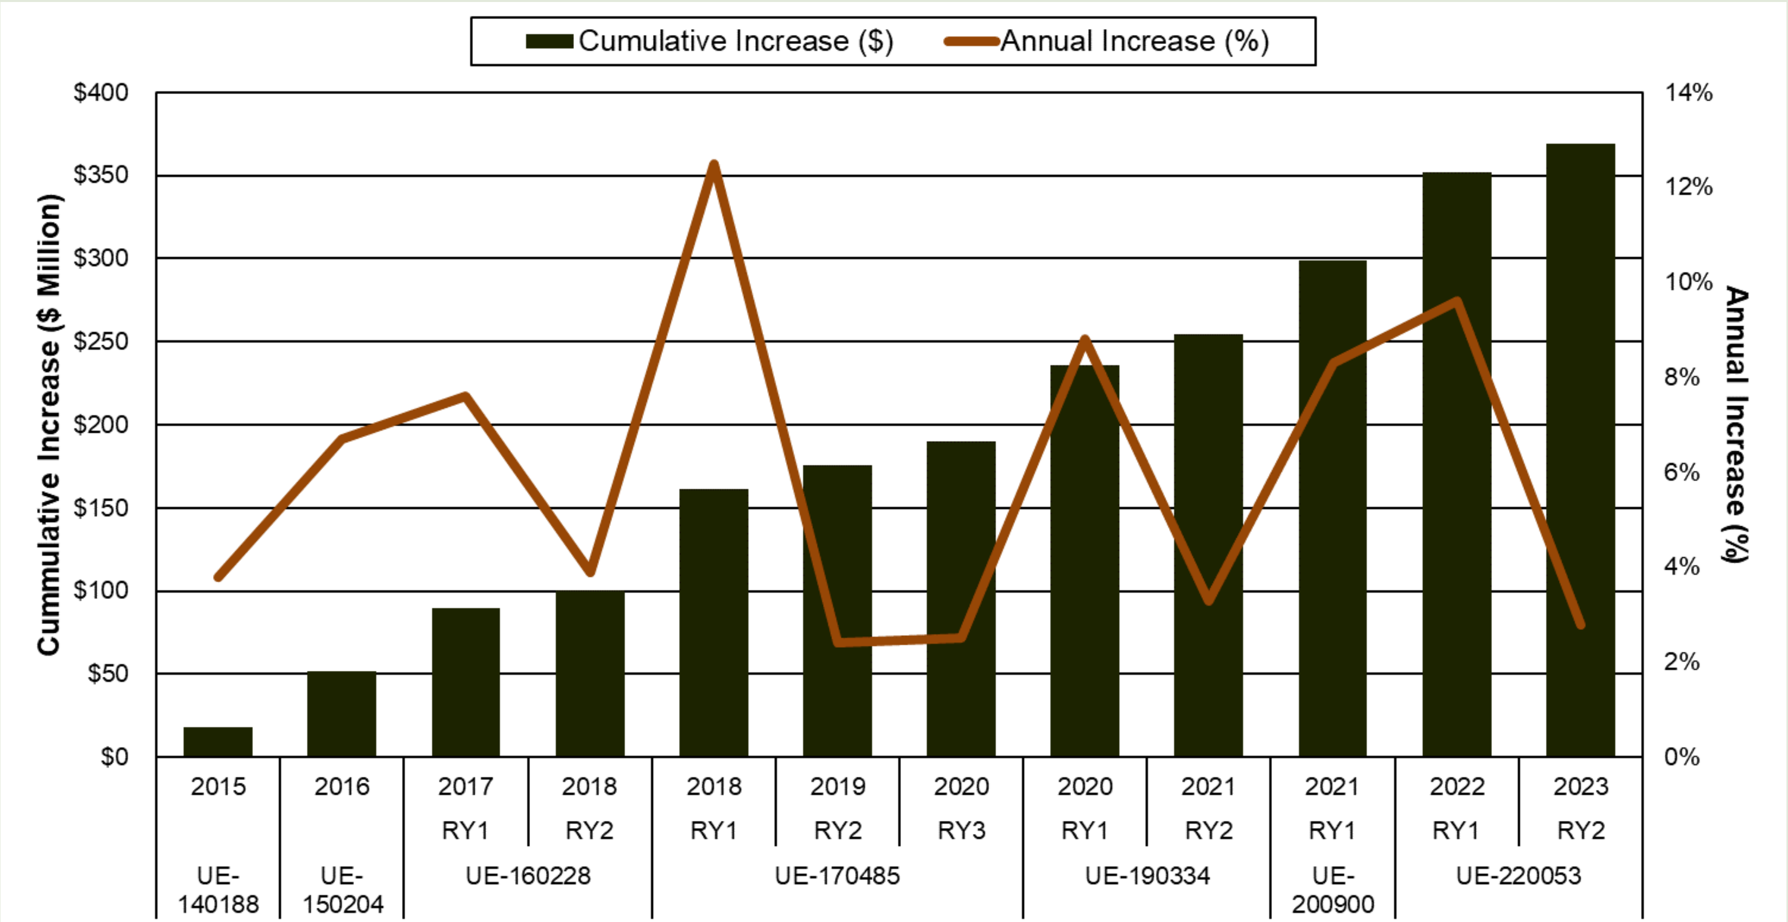


Exhibit OPC (A)-13
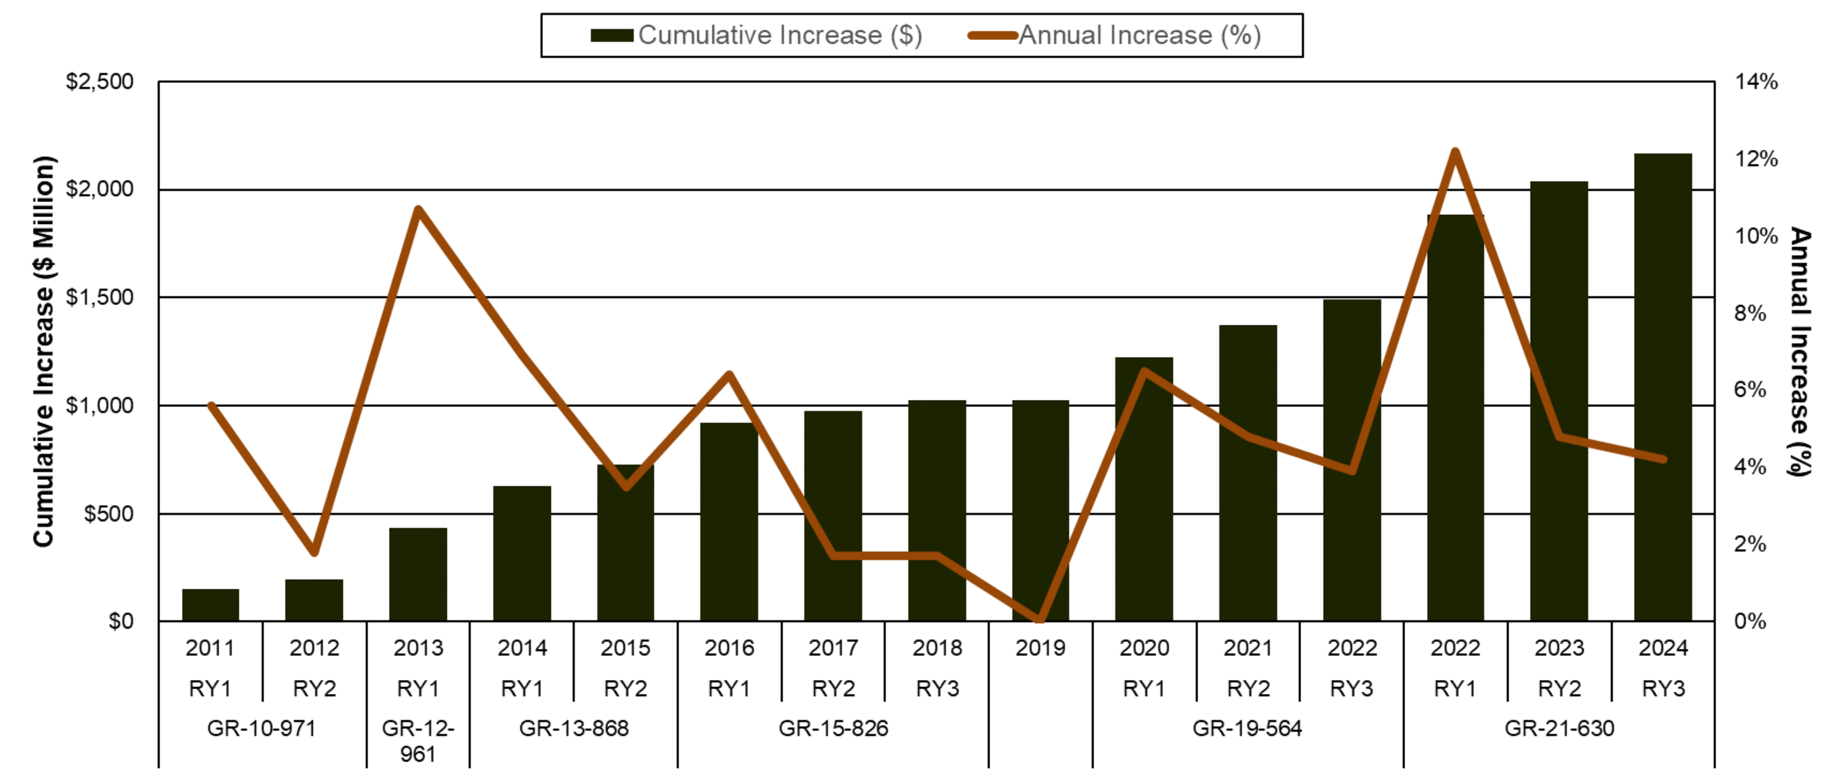
Formal Case No. 1176
David E. Dismukes, Ph.D.
Page 26 of 87

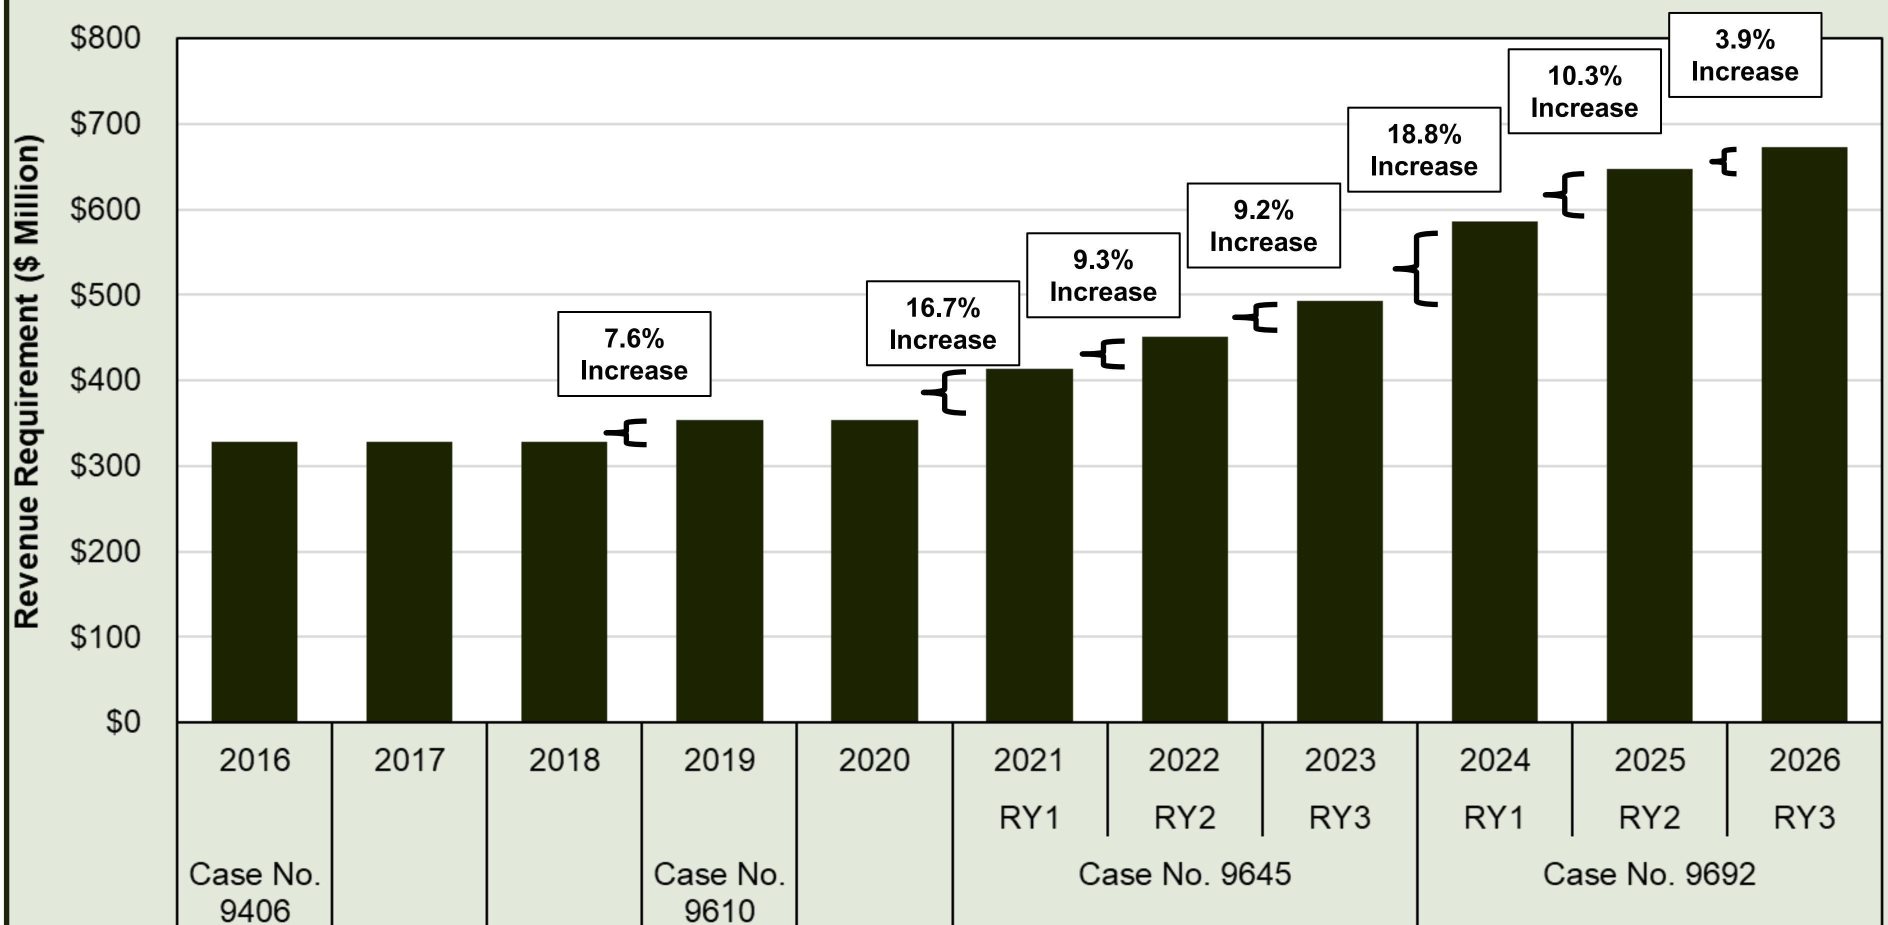
MYRP deficiency example: Xcel (Minnesota)

Xcel, under alternative regulation, has seen **cumulative rate increases of more than $2.2 billion since 2011 (5 percent per year)**.



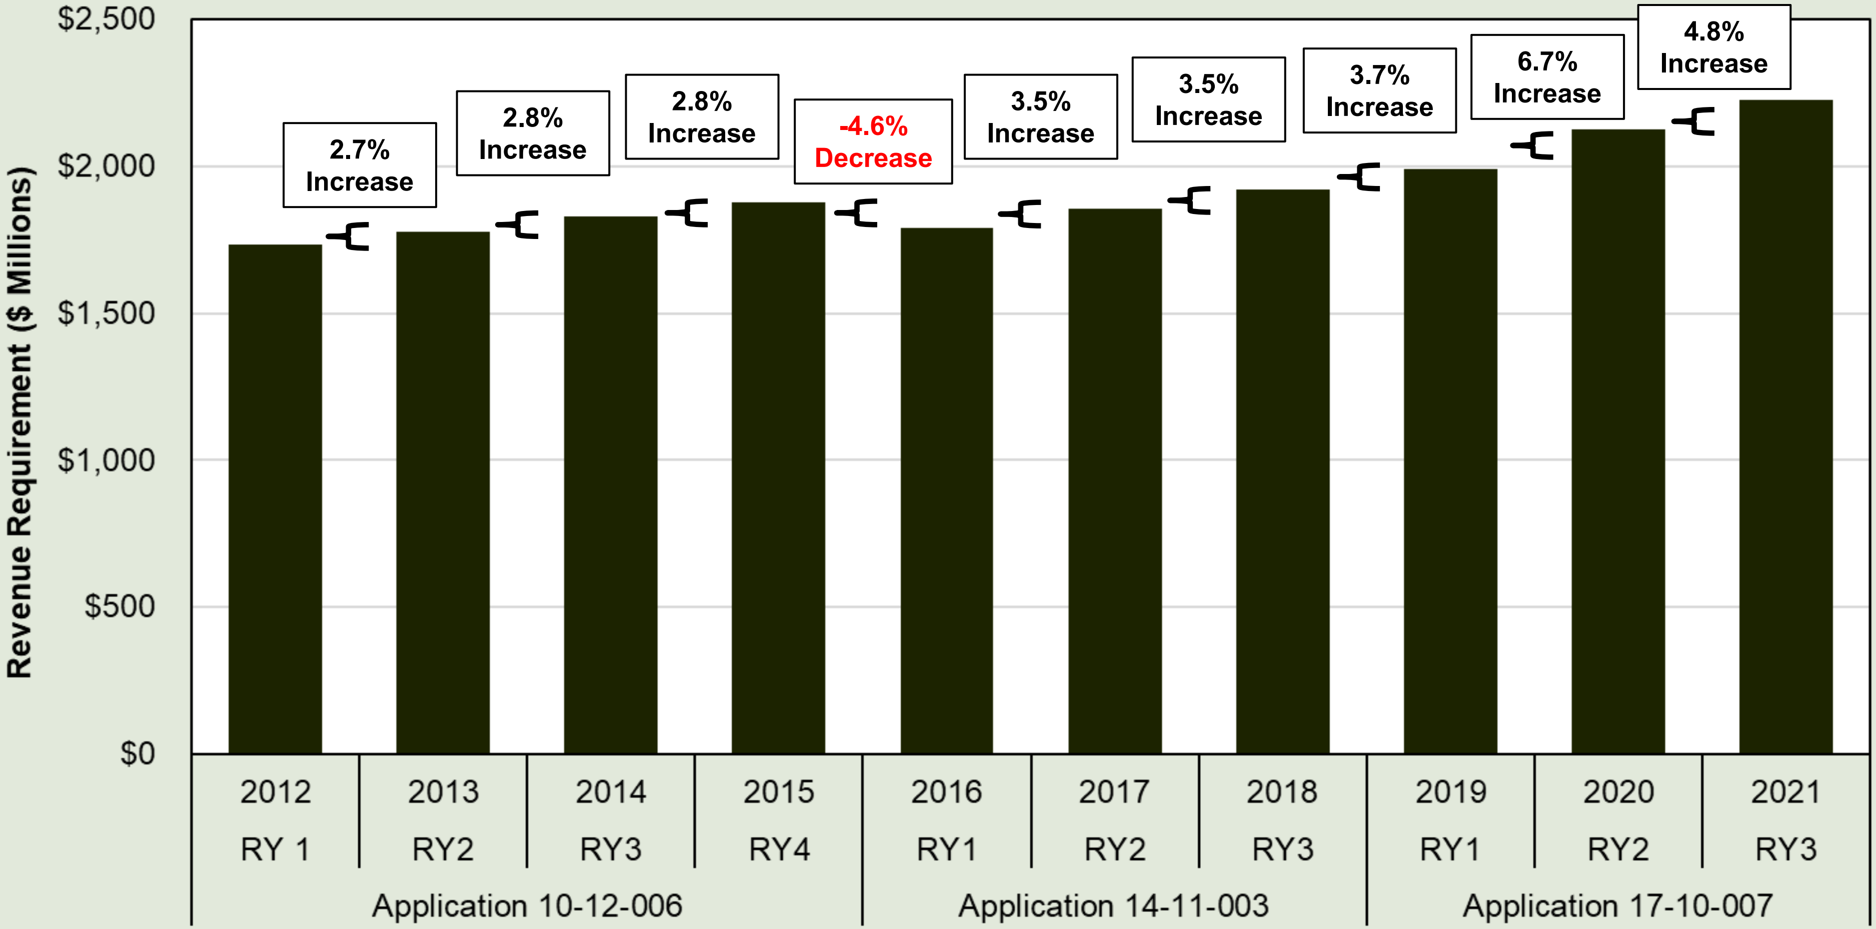
MYRP deficiency example: Baltimore Gas & Electric (Maryland)

From 2016 to 2020, BG&E saw one rate increase of 7.6%. **Since adopting alternative regulation, it has seen an average annual increase of 15%.**



MYRP deficiency example: San Diego Gas & Electric (California)

Under alternative regulation, SDG&E saw only one rate decrease in the past 10 years. **Rates grew at an average of 3.2% each year.**



MYRP proposals are stimulating community opposition.

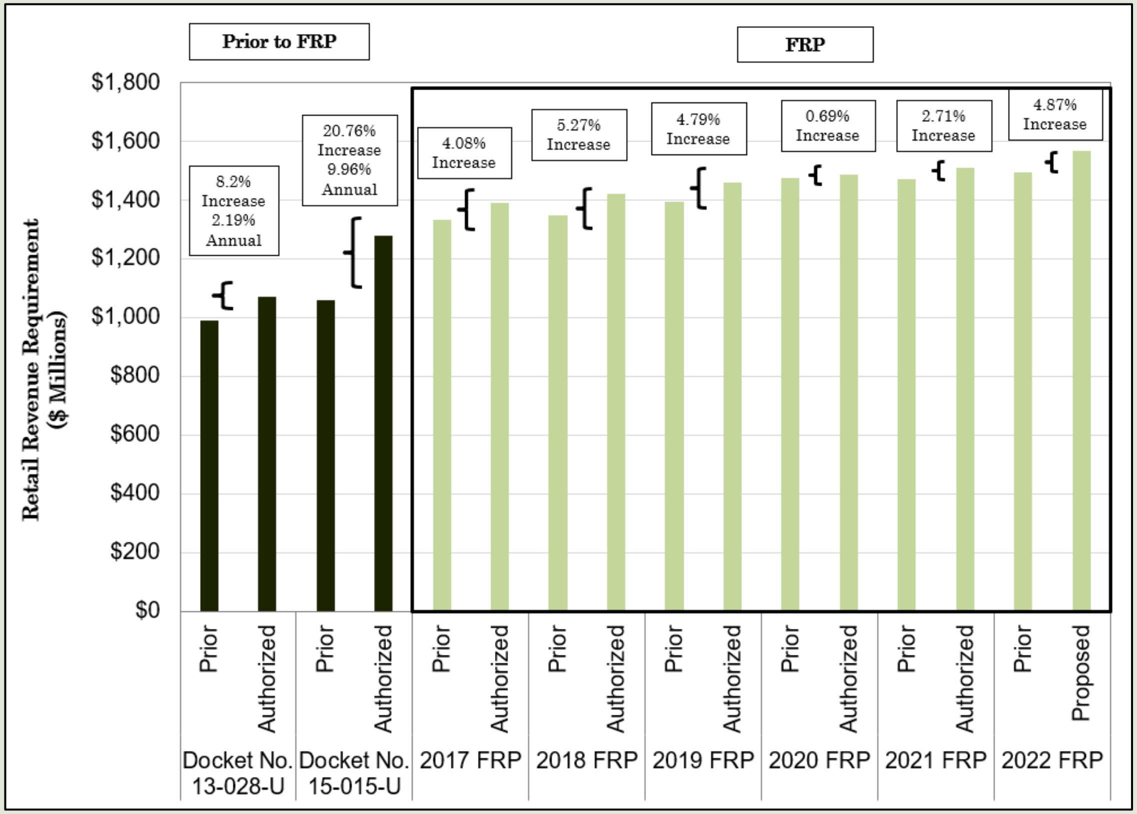
Criticism of MYRP use is not unique to utility regulatory experts, as community organizations have also expressed concerns. For instance, the executive director of Economic Action Maryland strongly criticized Baltimore Gas and Electric's ("BGE's") performance during its MYRP pilot program and its requested extension, observing:

> [B]efore the evaluation of the first [MYRP] pilot program is completed, BGE is back asking for a second multiyear rate increase. Essentially, BGE is asking for our trust and for us to pay rate increases based on what they expect to spend. BGE seeks to shift the costs of their infrastructure investments to customers while reaping the profits from these investments. A multiyear proposal incentivizes BGE's desired spending spree when what is needed is prudent oversight and review by the PSC.
>
> Rate increases in 2022 and 2023 are creating undue hardship for households across Central Maryland, particularly in Baltimore. Again, I can speak from experience. Since 2021, my BGE bills have increased by $200 per month, or $2,400 per year, while my consumption remains unchanged. … While this cost increase is a hardship for some middle-class families like mine, it is catastrophic for many families my nonprofit organization supports. … An increase in utility costs will hurt working families living paycheck-to-paycheck, forcing them to make impossible choices between keeping the lights on or keeping food on the table.

Source: "Commentary: BGE rate increase unaffordable for many in Maryland," The Baltimore Banner, Dec. 3, 2023.

Exhibit OPC (A)-13
Formal Case No. 1176
David E. Dismukes, Ph.D.
Page 30 of 87

FRP deficiency example: Entergy Arkansas ("EAI") rate increases.



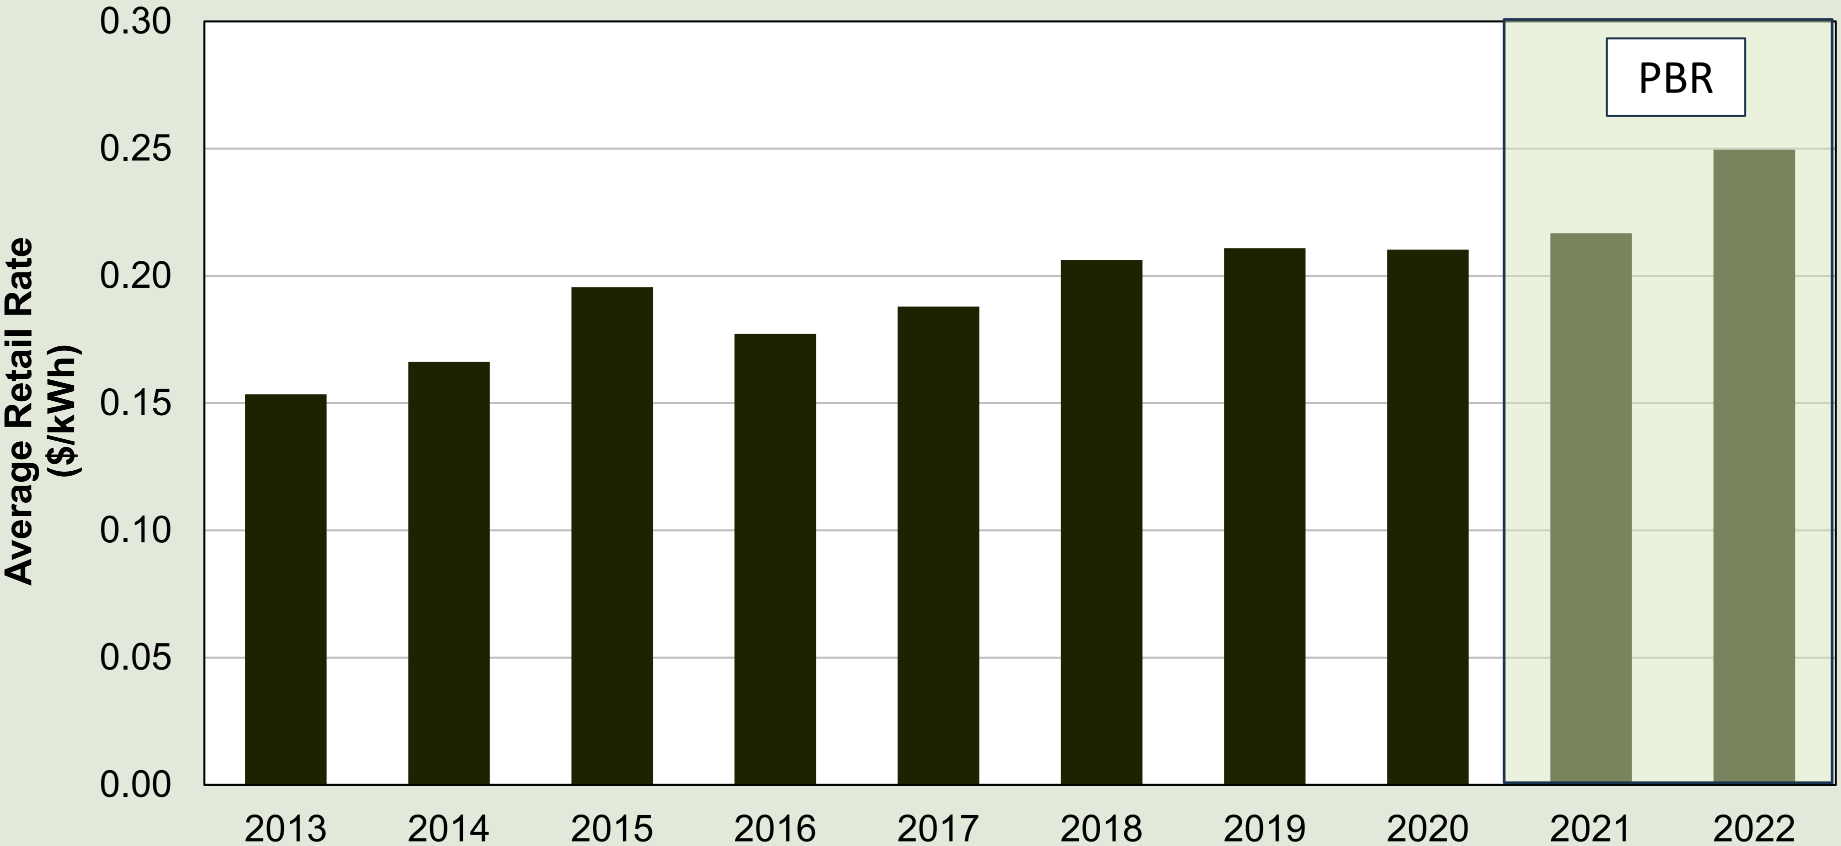
Unsurprisingly, most of EAI's FRP filings has been at a statutory cap. This is after the Company received a rather large pre-FRP "cast off" rate case.

Prior to alternative regulation, EAI's average rate increases were low, averaging 2.73 percent per year. Post alternative regulation, this increased to 3.74 percent annually or 6.83 percent including the FRP "cast off" rate case.

Source: Rate Case Compliance Filings, FRP Compliance Filings Attachment A and 2021 Evaluation Report, Attachment A.2-Extension

PBR deficiency examples: National Grid rate increases.

National Grid (Massachusetts Electric Company) saw rates **increase from $0.2103 per kWh in 2020 to $0.2496 per kWh in 2022, an increase of 18.7 percent over the course of its approved PBR plan.** When evaluating historic rates, **it is clear that PBR did not slow the pace of rate increases.**

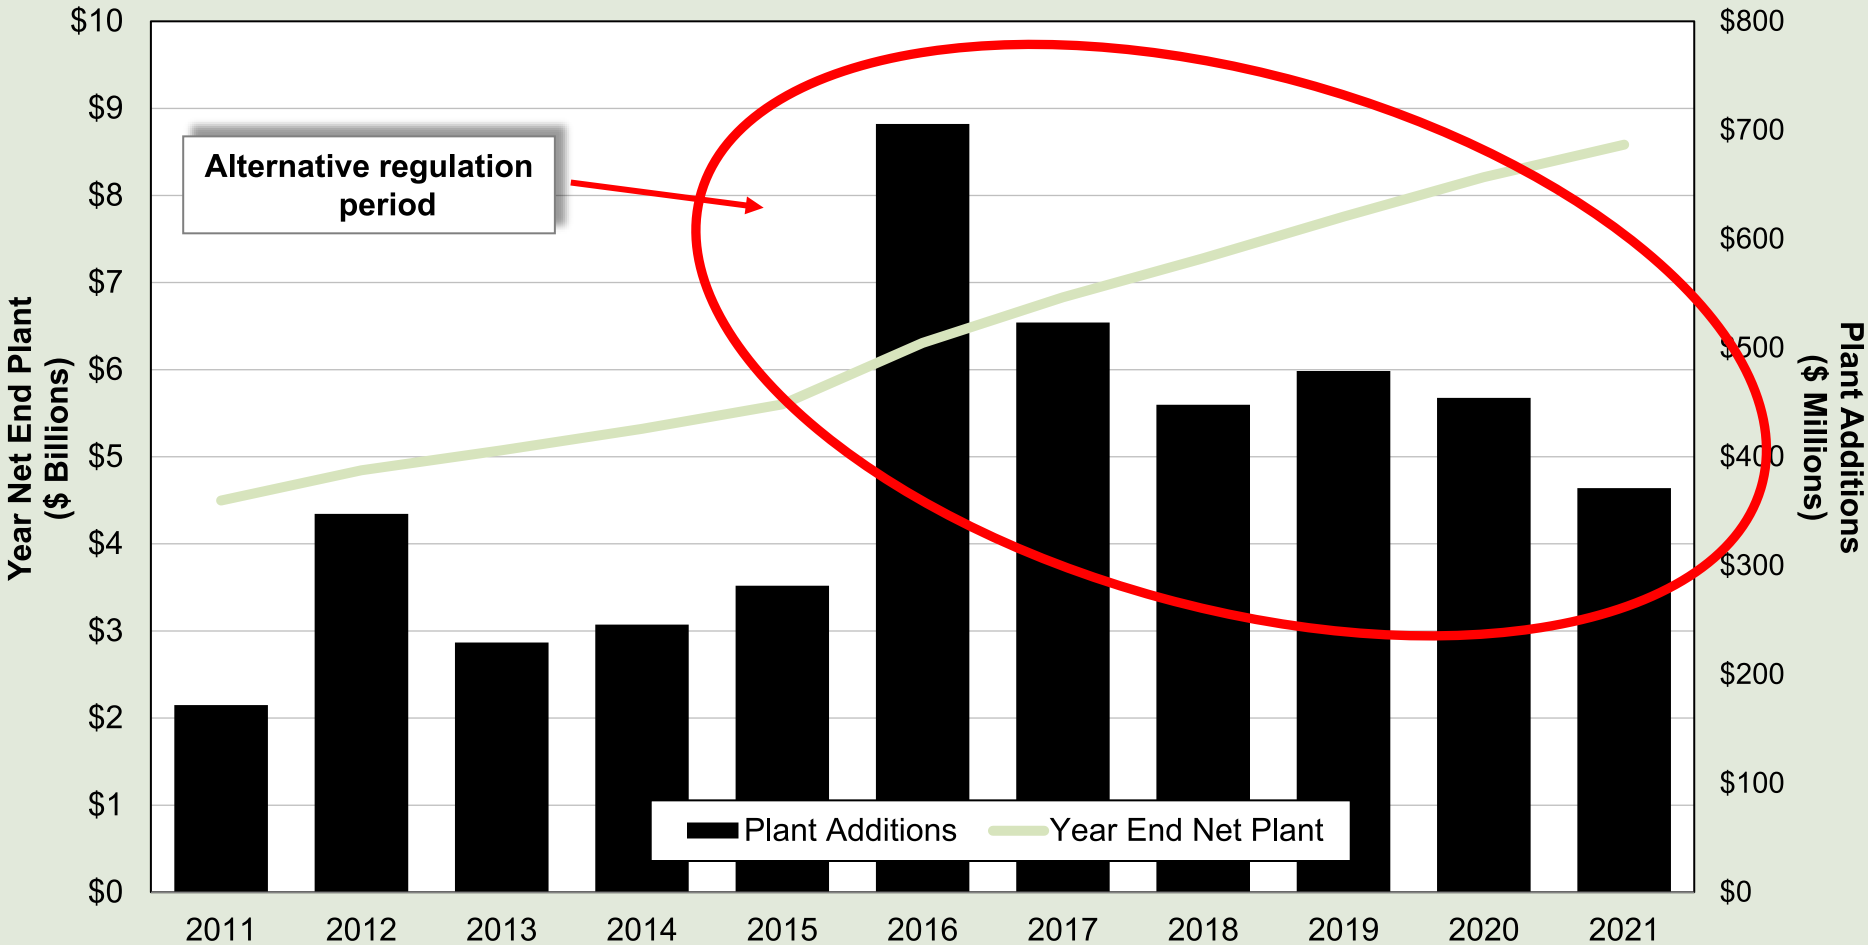


Source: EIA Form 826.

Section 4: Alternative regulation leads to operating inefficiencies

FRP deficiency example: EAI net plant growth

Net plant for EAI has almost doubled since 2011. In 2018, net plant additions amounted over to $700 million.



Source: FERC Form 1 as provided by S&P Global.

FRP deficiency example: concerns with Entergy Arkansas cost containment.

The **Arkansas Public Service Commission has repeatedly expressed concern about whether the FRRA is achieving the intended public policy objectives** (such as greater cost containment) envisioned by the Arkansas General Assembly, noting:

> The Commission expects all utilities to control their costs in a prudent and reasonable manner **and not utilize the FRP as an automatic yearly four percent rate increase.**[1]
>
> Many of the FRP processes, including a reduction in the time afforded for review, the use of projections, and the annual rate adjustments **do little to incentivize a utility to control its costs as compared to traditional ratemaking** …[2]

Source 1: Docket No. 255, Order No. 14, issued 12/13/2017, at 31. (Emphasis added.)
Source 2: Docket No. 420, Order No. 21, issued 7/5/2019, at 40. (Emphasis added.)

PBR deficiency examples: Eversource (NSTAR) operating cost efficiencies.

There is **no significant post-PBR cost efficiency (Massachusetts) – Eversource is still above regional peer average in operating costs per MWh.**

Section 5: Alternative regulation does not improve reliability

Concerns regarding MYRP reliance on projections.

MYRPs **establish rates based upon projected revenue, costs, and expenses**. Utilities can **over-estimate projected costs and expenses to insulate it** from having to bear unforeseen costs or expenses and perhaps.

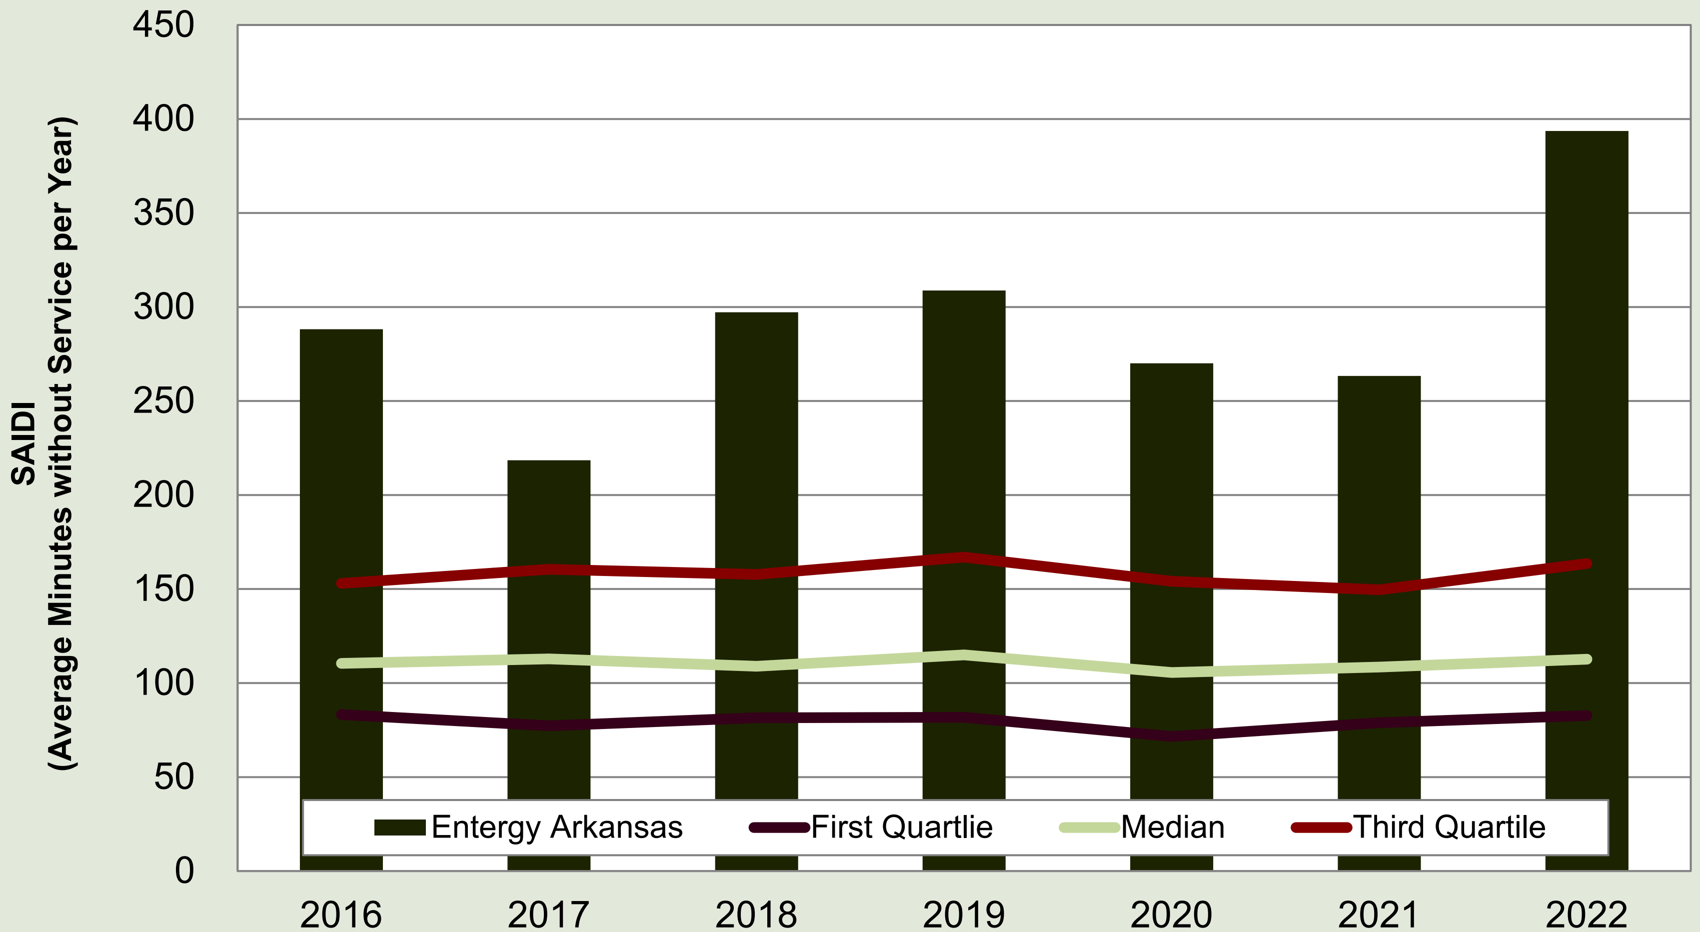
The **Connecticut Public Utility Regulatory Authority ("Authority")**[1] criticized United Illuminating Company ("UI") and its MYRP for its **incorrectly estimated seven-year period capital spend** including anticipated **investments in reliability,** such as storm resilience, substation flood mitigation, step down bank removal projects, substation getaway projects, and perimeter feeder ties projects.

The Authority calculated that UI had underspent its allowed capital budget for the years 2013 through 2019 **by more than $80 million** noting **"For multi-year rate plans, this level of underspending introduces risk that customers pay for plant additions that are not actually in service."**

Source: Proposed Final Decision, CT Public Utility Regulatory Authority Docket No. 22-08-08, July 21, 2023, pp. 44-48.

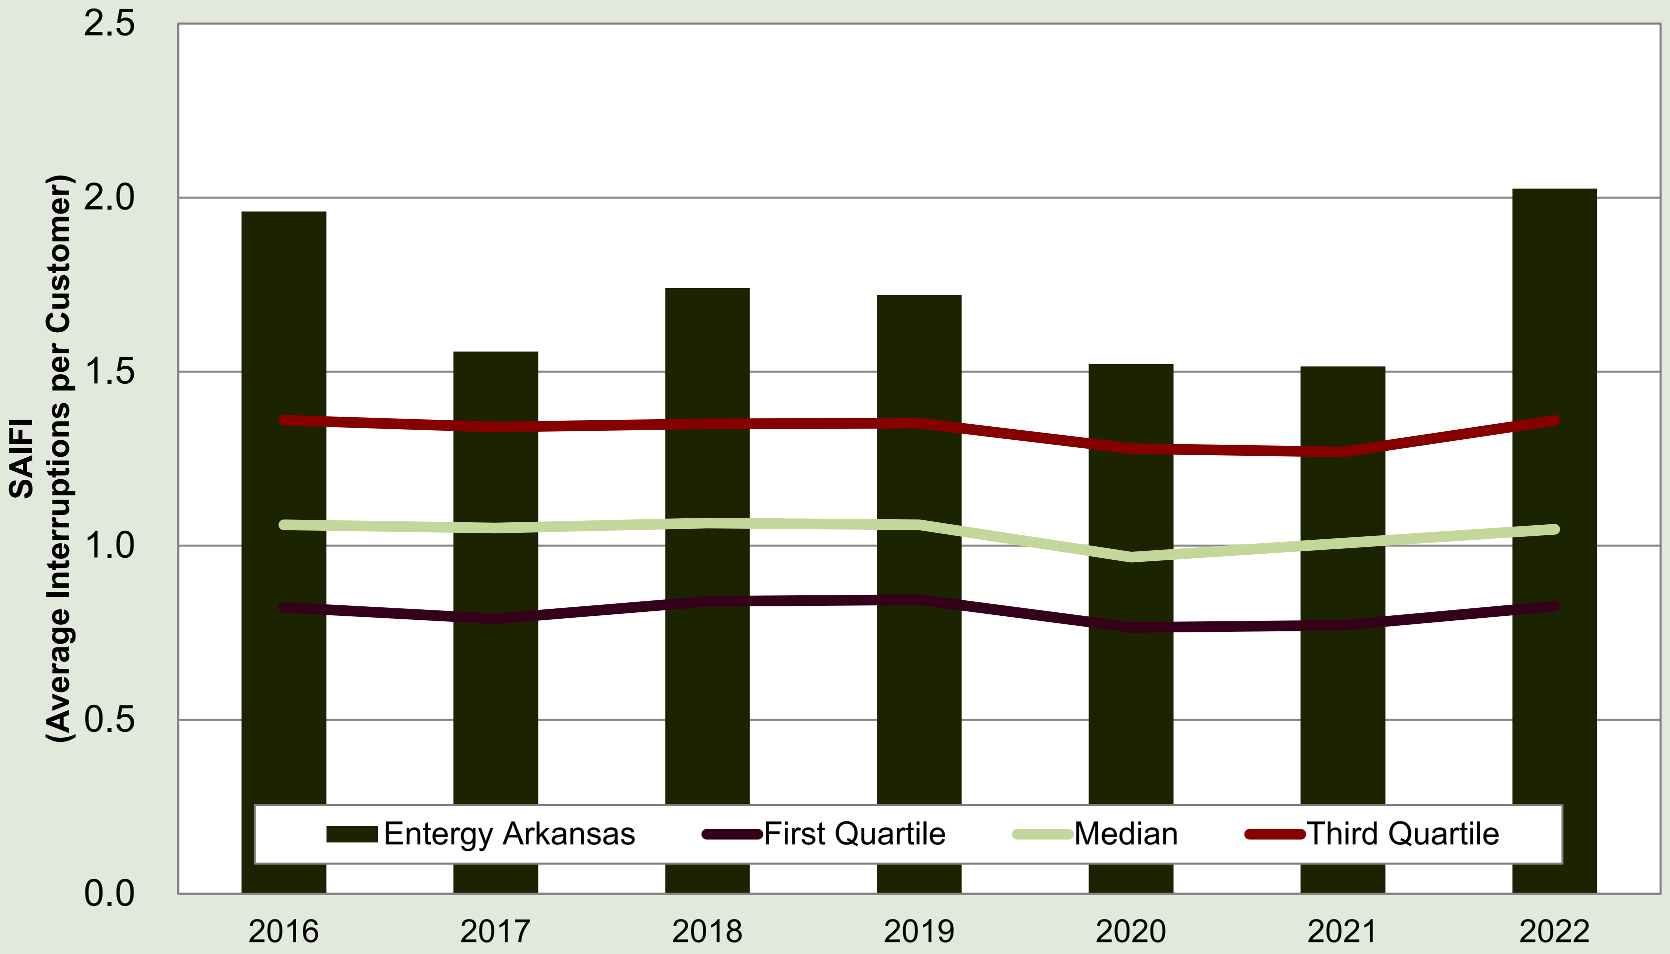
FRP deficiency example: Entergy Arkansas reliability performance ("SAIDI").

FRP has not resulted in any meaningful reliability improvement for EAI falling well into the **bottom fourth quartile** of utility SAIDI performance.



FRP deficiency example: Entergy Arkansas reliability performance (“SAIFI”).

EAI’s SAIFI performance is in the **bottom fourth quartile of peer utilities**.



FRP deficiency example: Entergy Mississippi reliability performance.

EAI's sister utility in Entergy Mississippi ("EMI") **also under an FRP, acknowledged its reliability performance has not met customers' expectations** despite being afforded a special alternative regulation framework.

For Immediate Release

Entergy Mississippi acknowledges challenges in June storm response

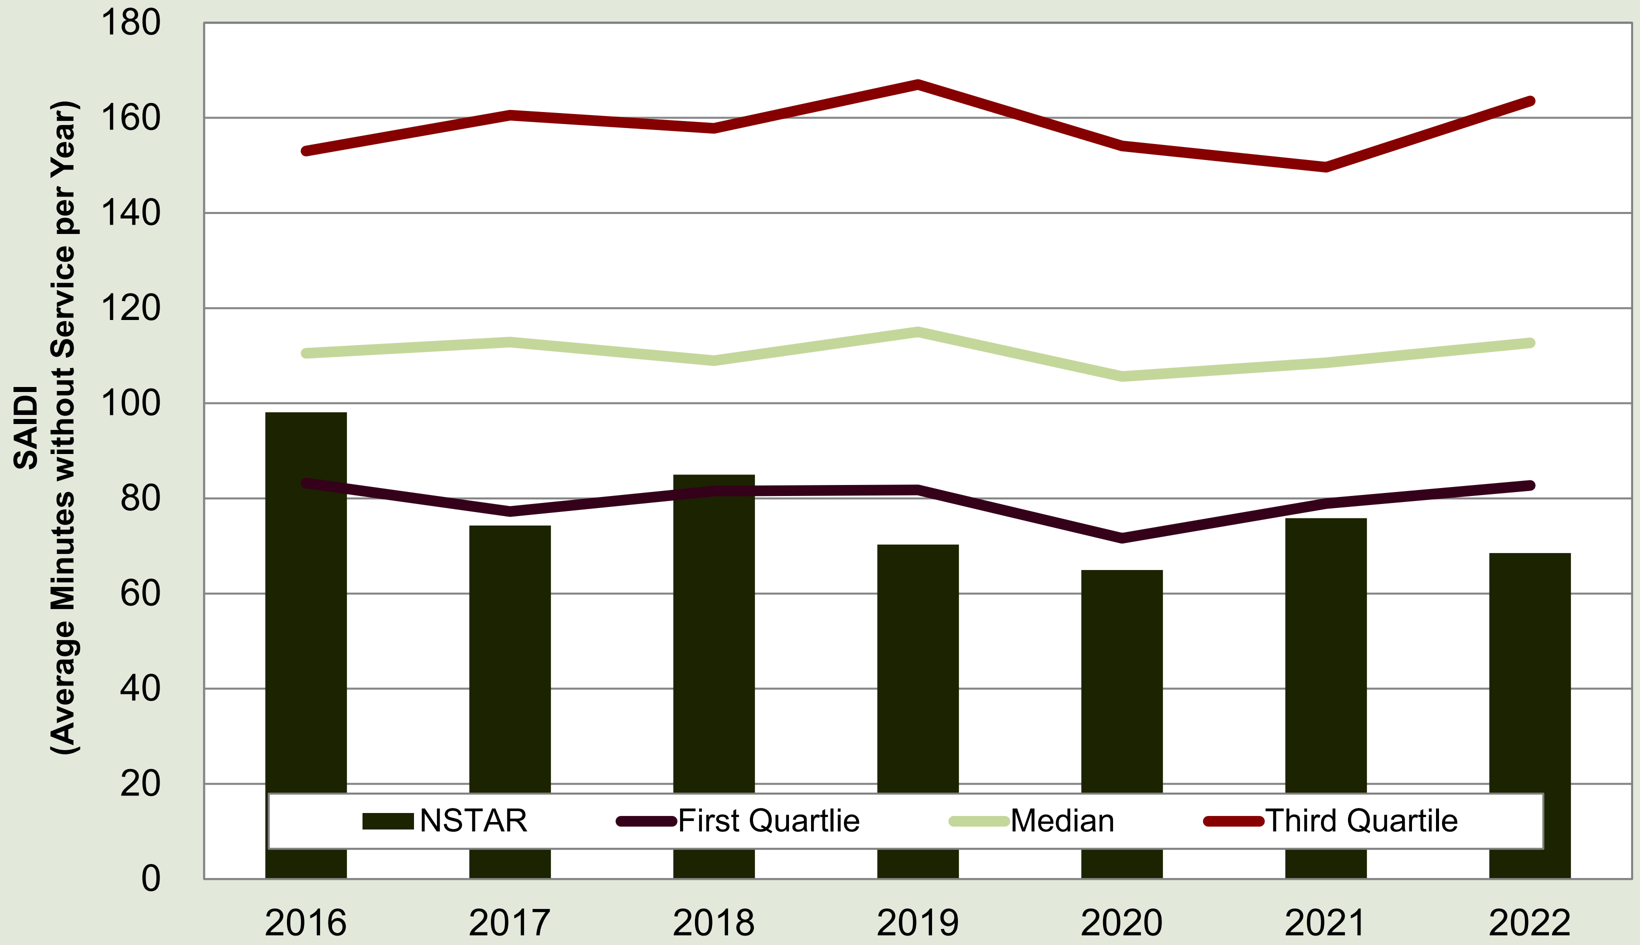
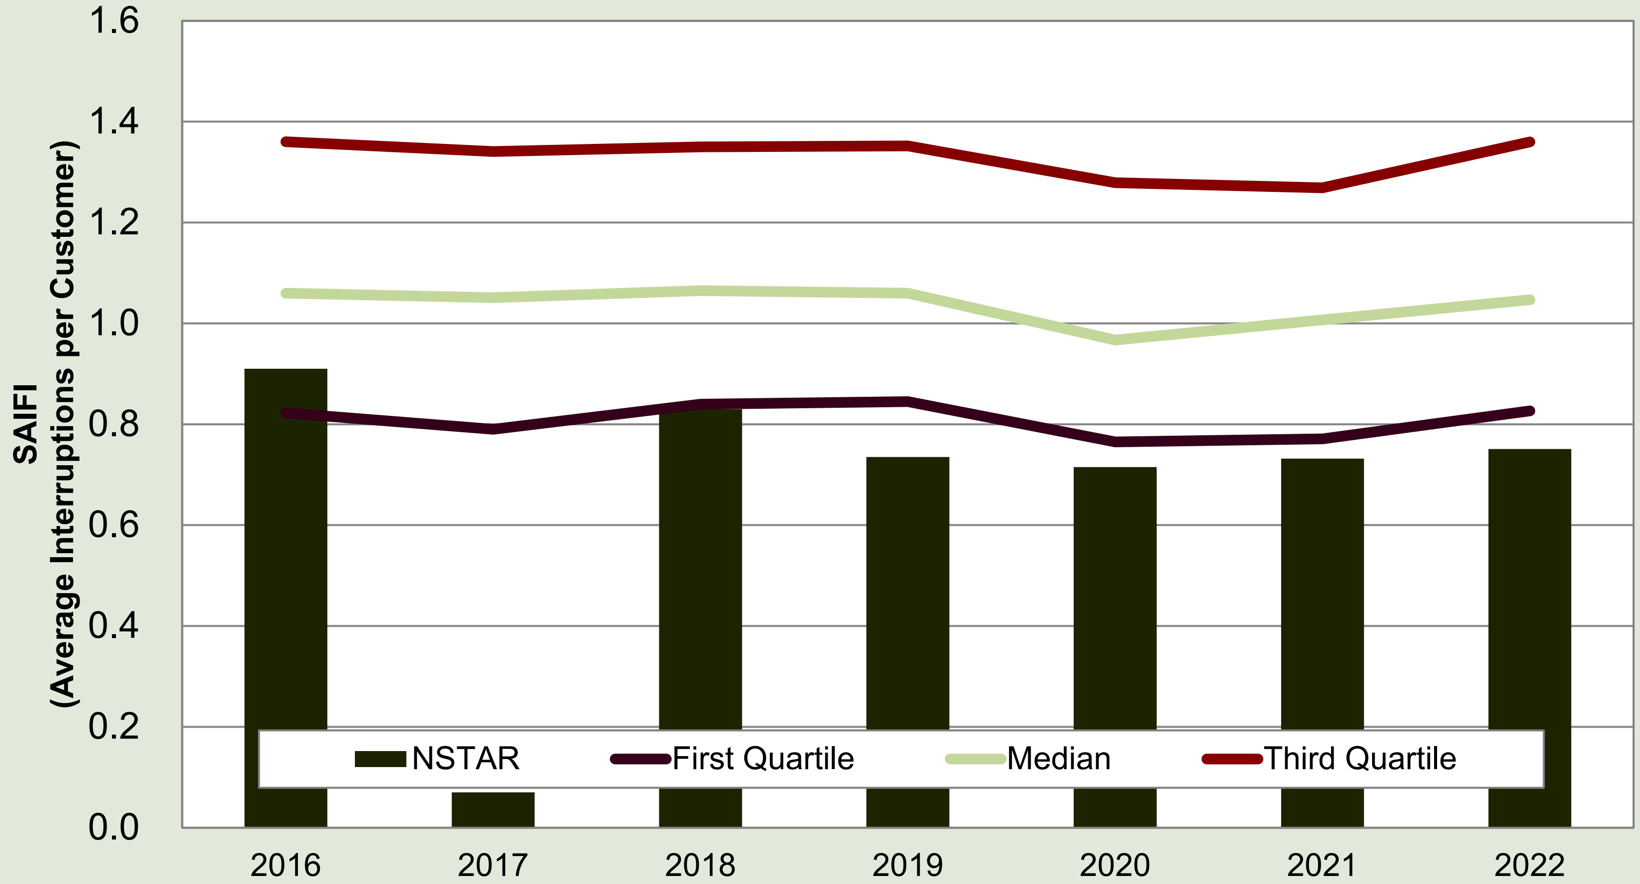
NSTAR has seen inconsistent SAIDI scores over the years.



Example: NSTAR reliability comparison (SAIFI)

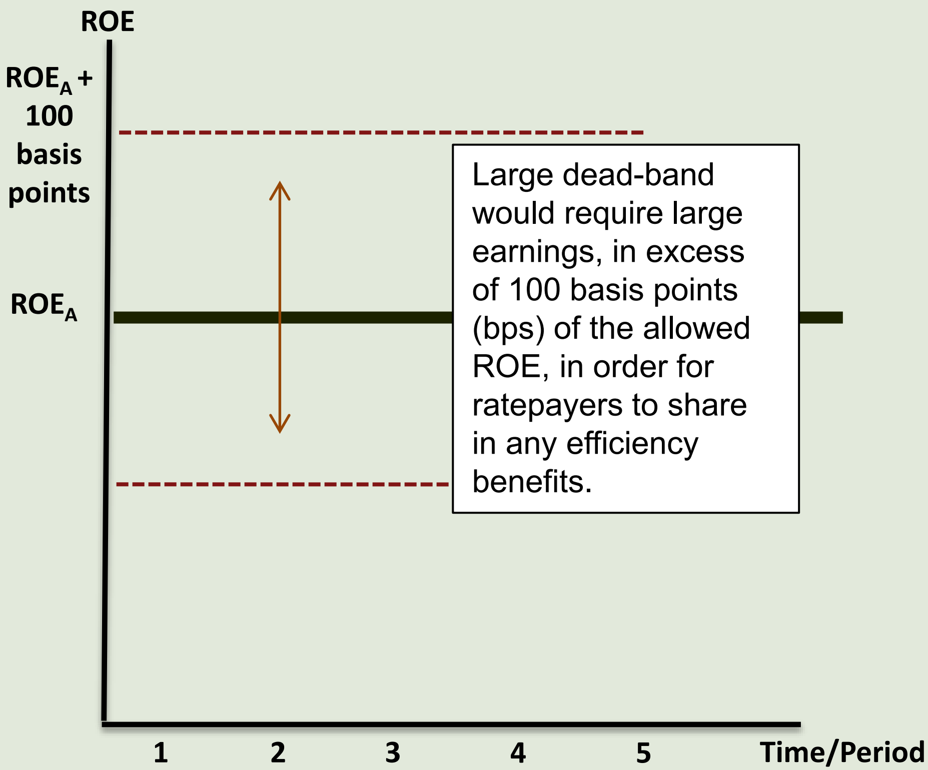
NSTAR has seen relatively flat SAIFI scores over the last few years.



Section 6: Alternative regulation leads to utility gamesmanship

Earnings sharing in alternative regulation.

Most **alternative regulation is paired with earnings sharing mechanisms** that share purported efficiency gains, **as measured through excess earnings**, with ratepayers.



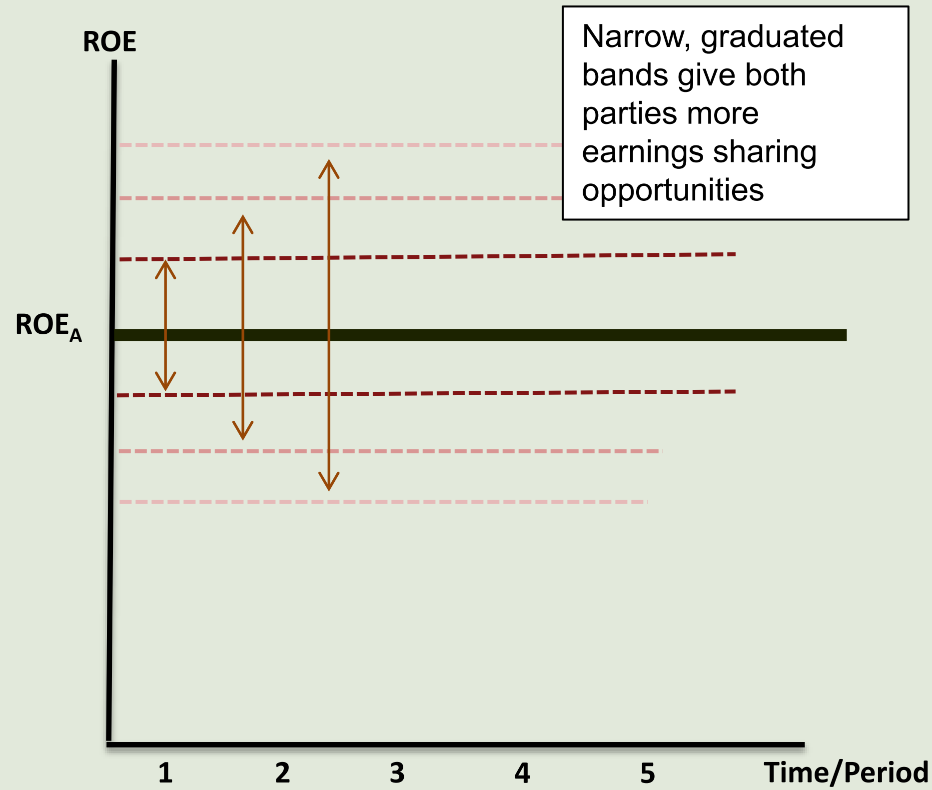


Exhibit OPC (A)-13
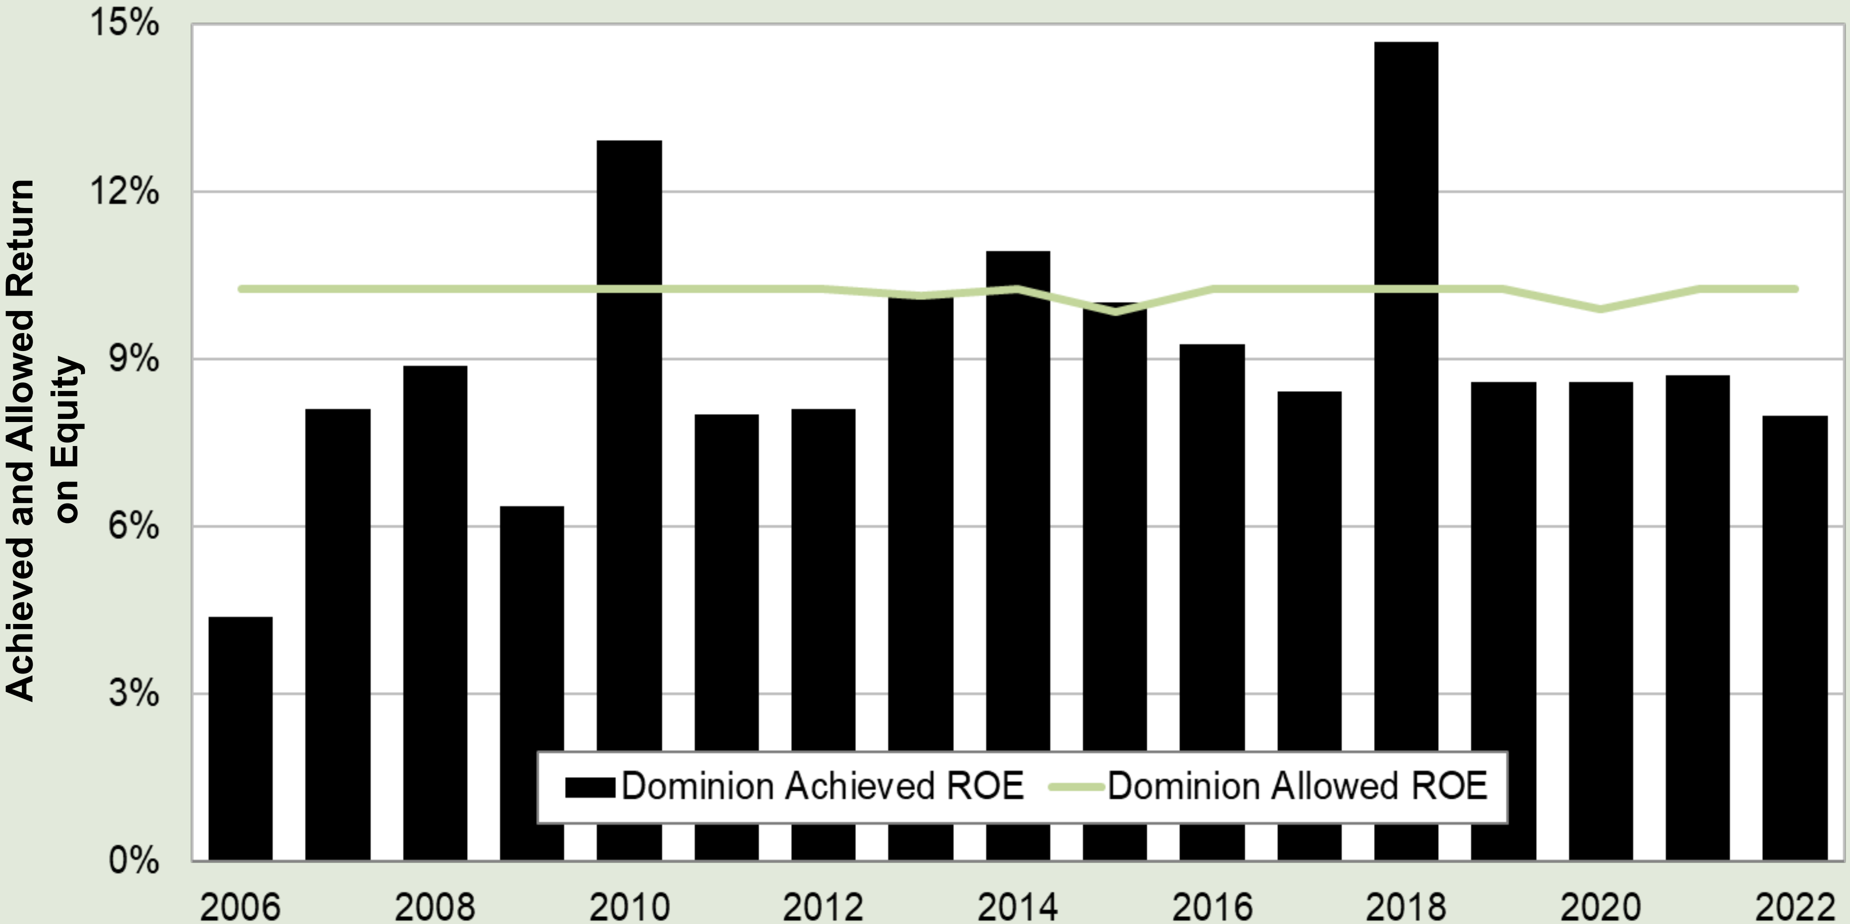
Formal Case No. 1176
David E. Dismukes, Ph.D.
Page 59 of 87

FRP deficiency example: Dominion SC earnings sharing mechanism.

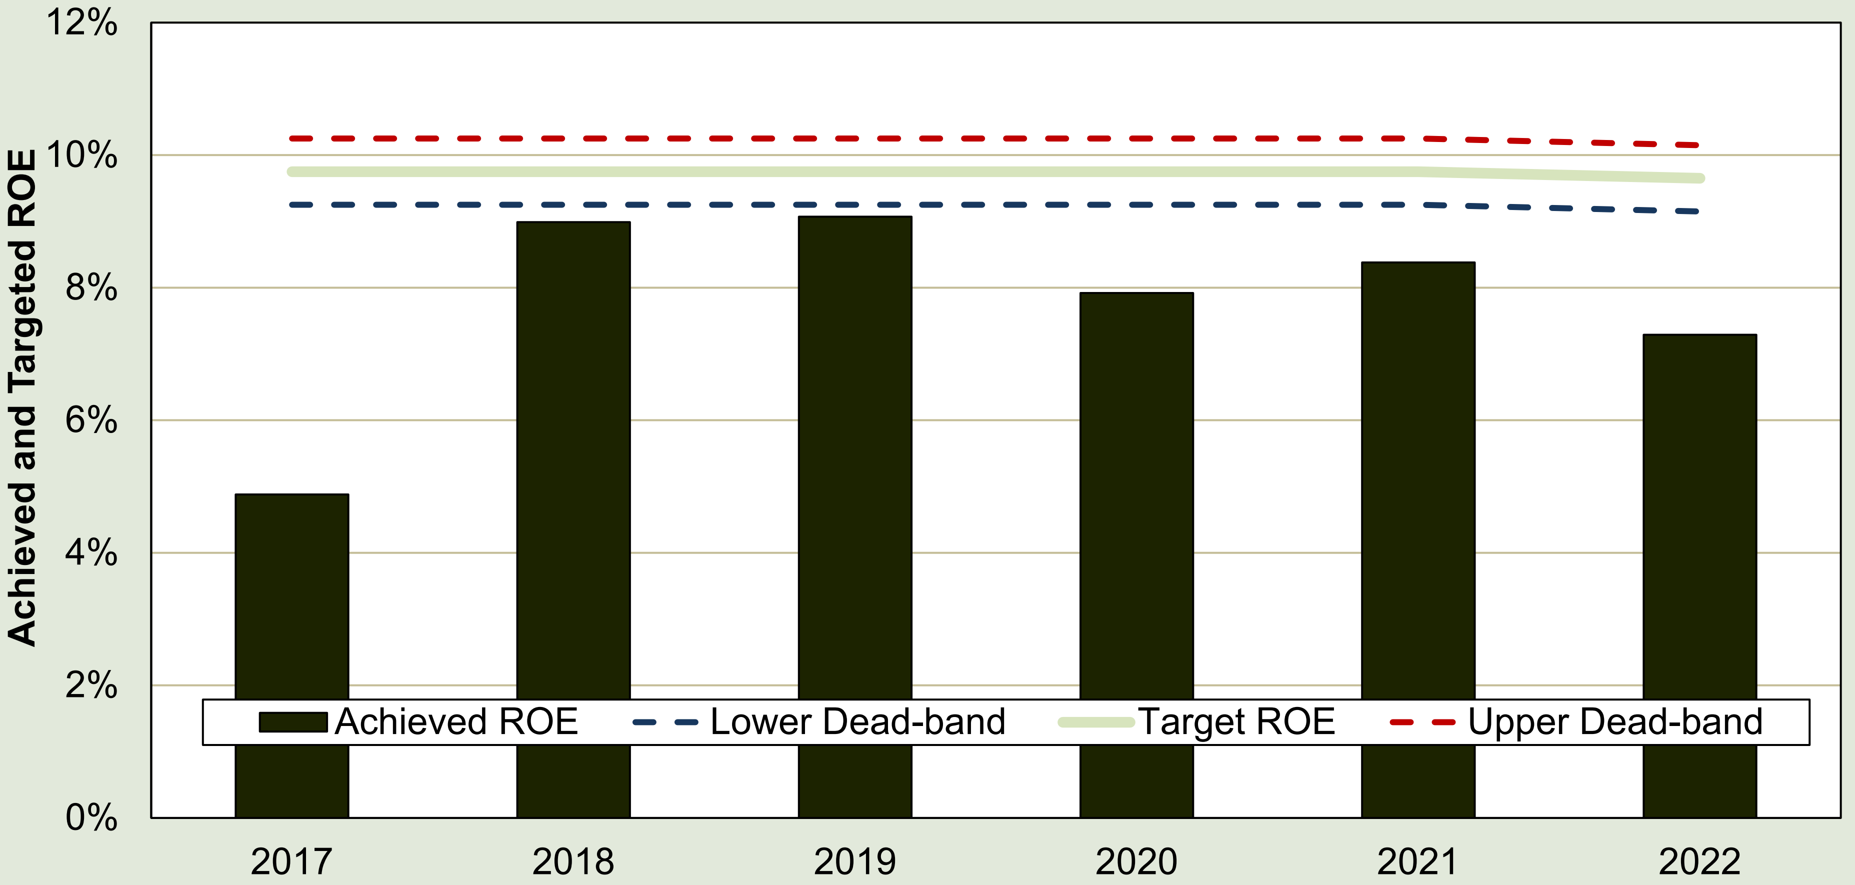
DESC's **achieved ROE has fallen below its allowed ROE deadband in 13 of 17** different FRP reporting periods since FRP was implemented in 2006.



Source: RSA filings and Annual Reports

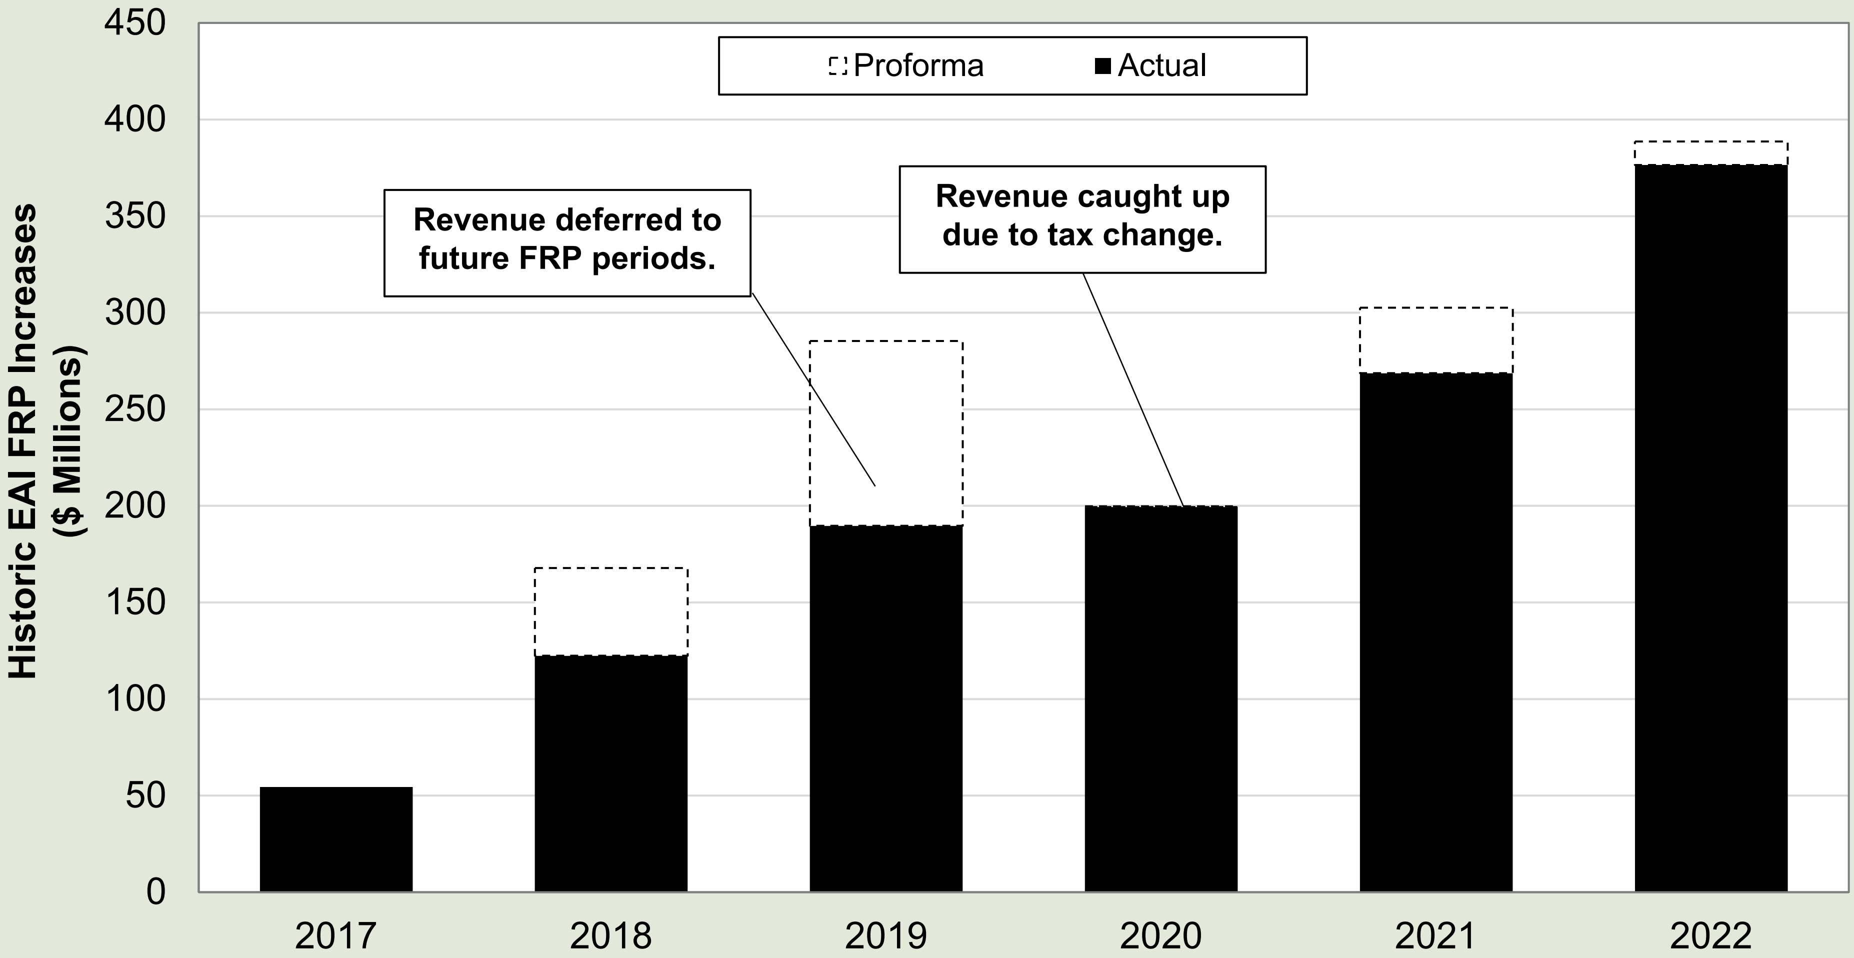
FRP deficiency example: Entergy Arkansas strategic earnings.

EAI has never shared any benefits with ratepayers through its earnings sharing mechanism. Instead, it has **been guaranteed a *de facto* statutorily-allowed four percent rate increase every year**.



FRP deficiency example: EAI revenue alternative regulation increases

EAI has **booked expenses/investments in excess of rate cap** to **assure those investments are "used and useful" for future ratemaking purposes.**



Source: Commission Filings.

Section 7: Pepco Performance

Section 7.1: Retail rates and revenues

Regional non-fuel residential rates ($ per kWh).

Pepco's non-fuel residential rates have been consistently at or above the regional average on a dollar per kWh basis. In 2022 Pepco's residential rates fell below the regional average due to significant rate increase in Duquesne Light Company and PECO Energy Company.

ACADIAN CONSULTING GROUP

Operating Expense Efficiencies

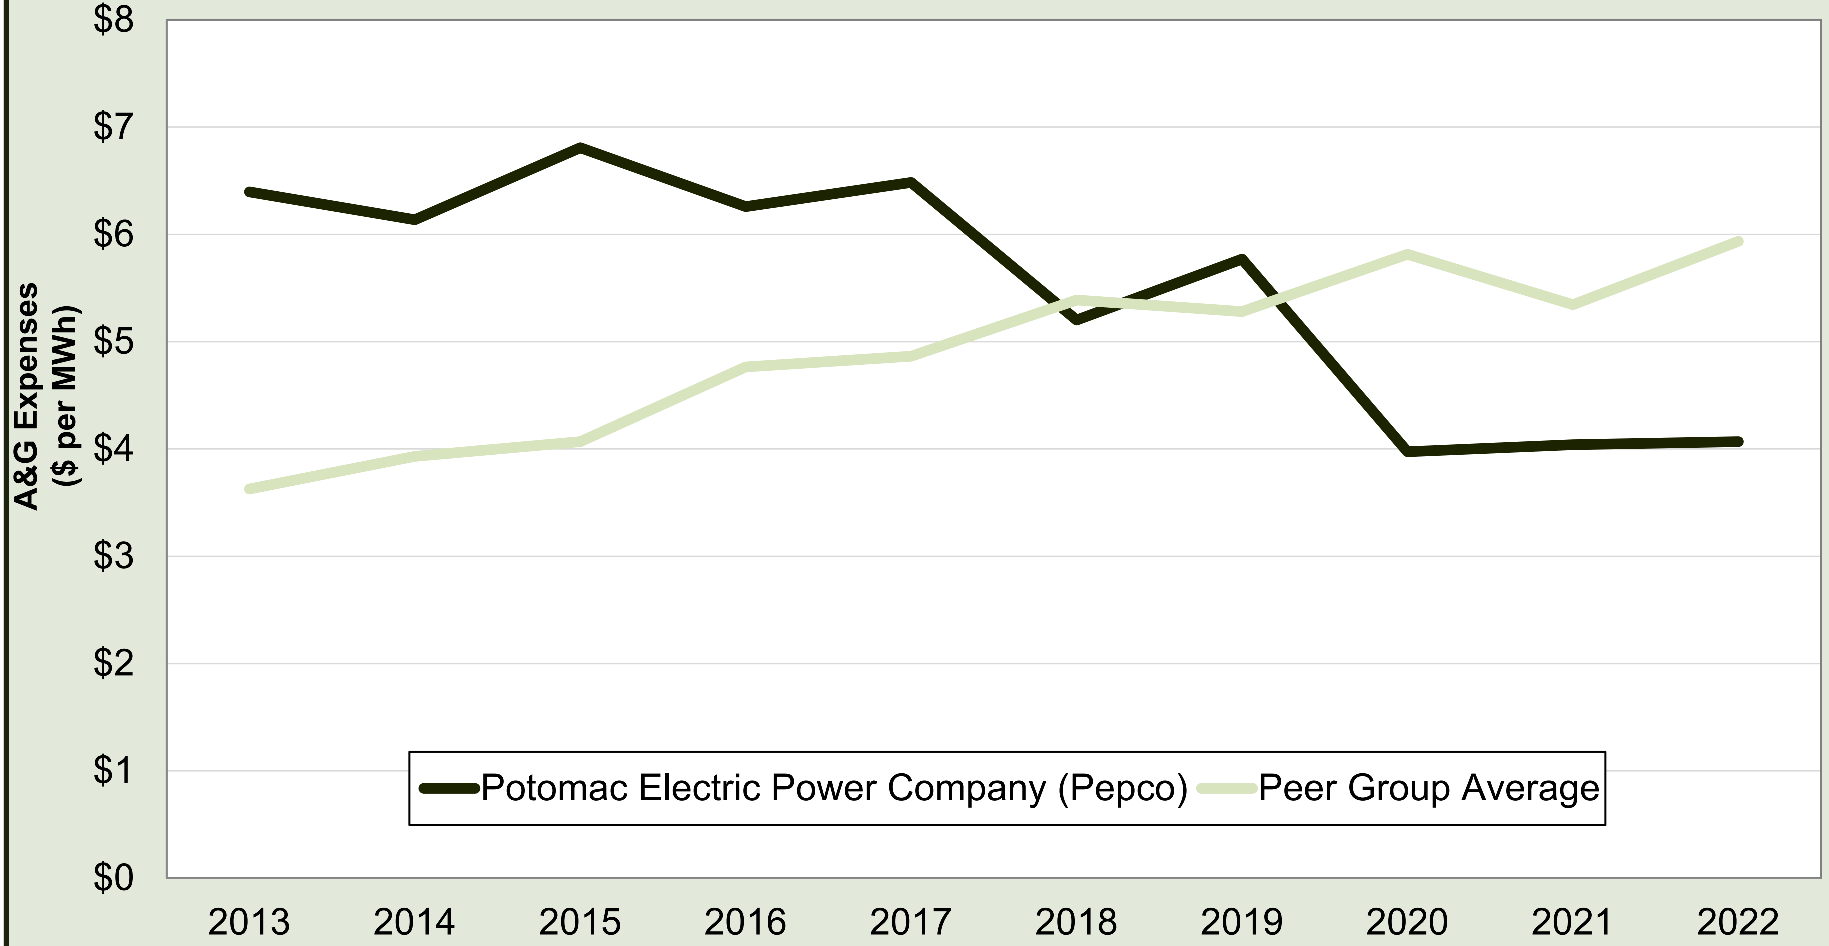
Trends: A&G expenses ($ per MWh).

Starting in 2018, Pepco has seen improvement compared to regional peers. A&G expense has been level since 2020.

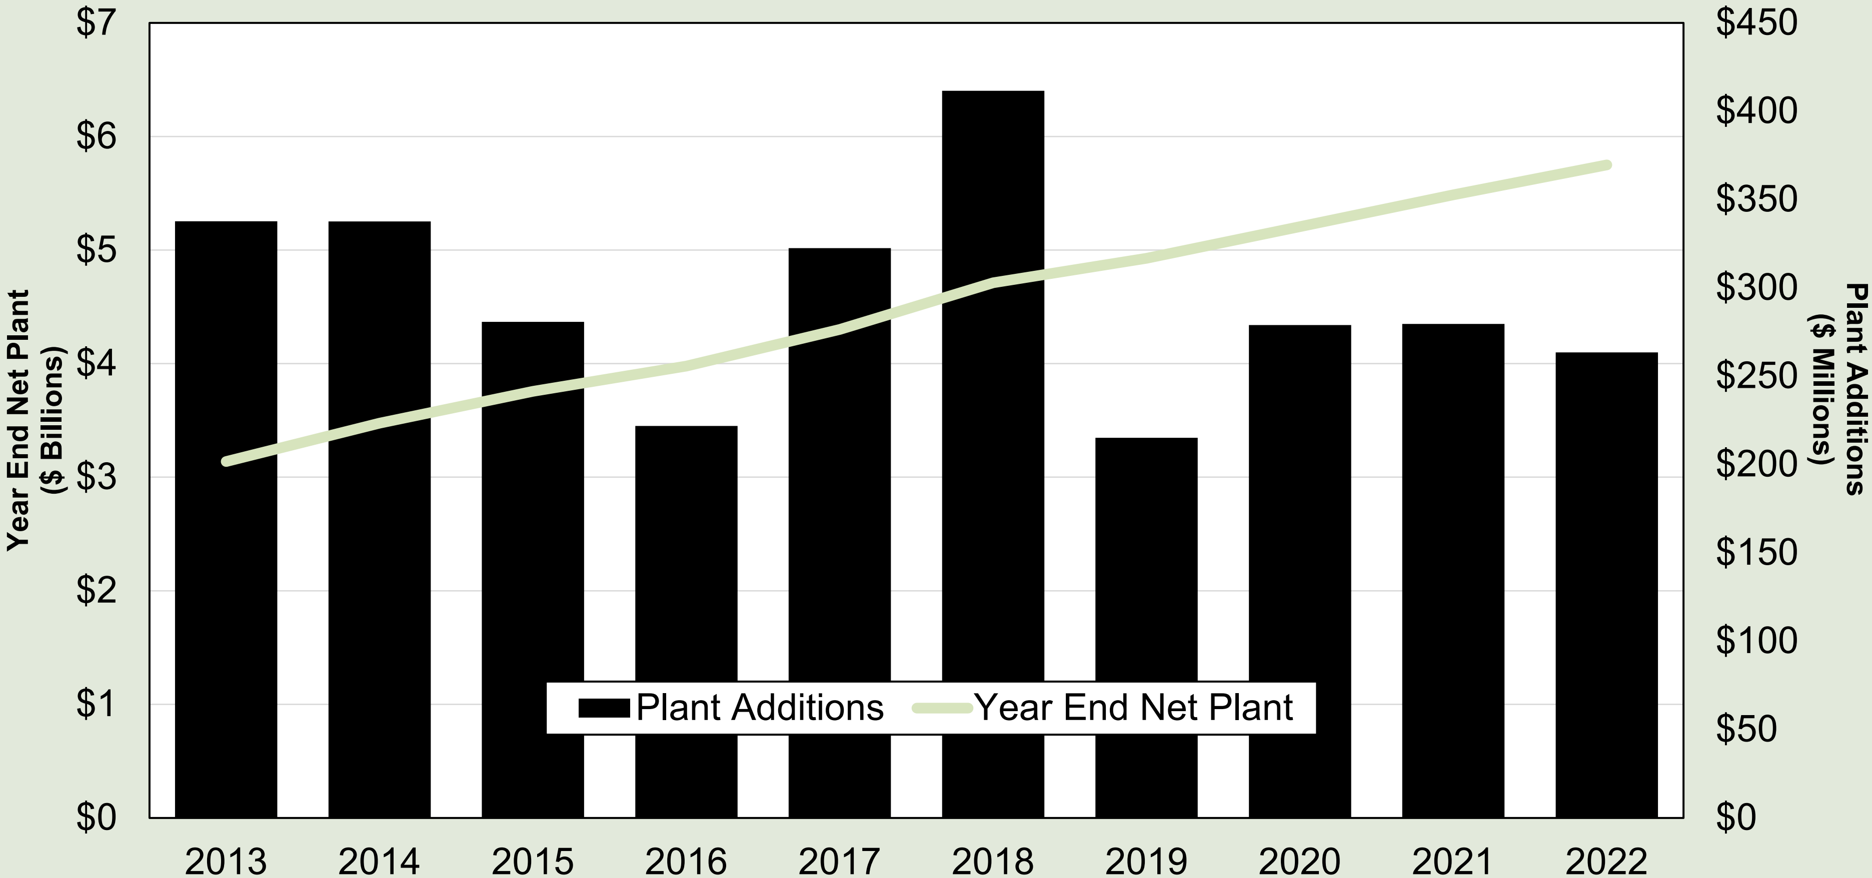


Source: FERC Form 1 as provided by S&P Global.

Section 7.3: Capital investment efficiencies

Pepco net distribution plant growth.

Pepco has seen considerable growth in net distribution plant. It increased from $3.1 billion in 2013 to $5.7 billion in 2022. The largest increase was in 2018 with $411 million added.



Source: FERC Form 1 as provided by S&P Global.

Regional net distribution plant ($/MWh) investment.

Net distribution plant in service in Pepco's service territory has constantly outpaced regional peer utilities since 2013. This disparity has grown in recent years with the growth in distribution plant investments.

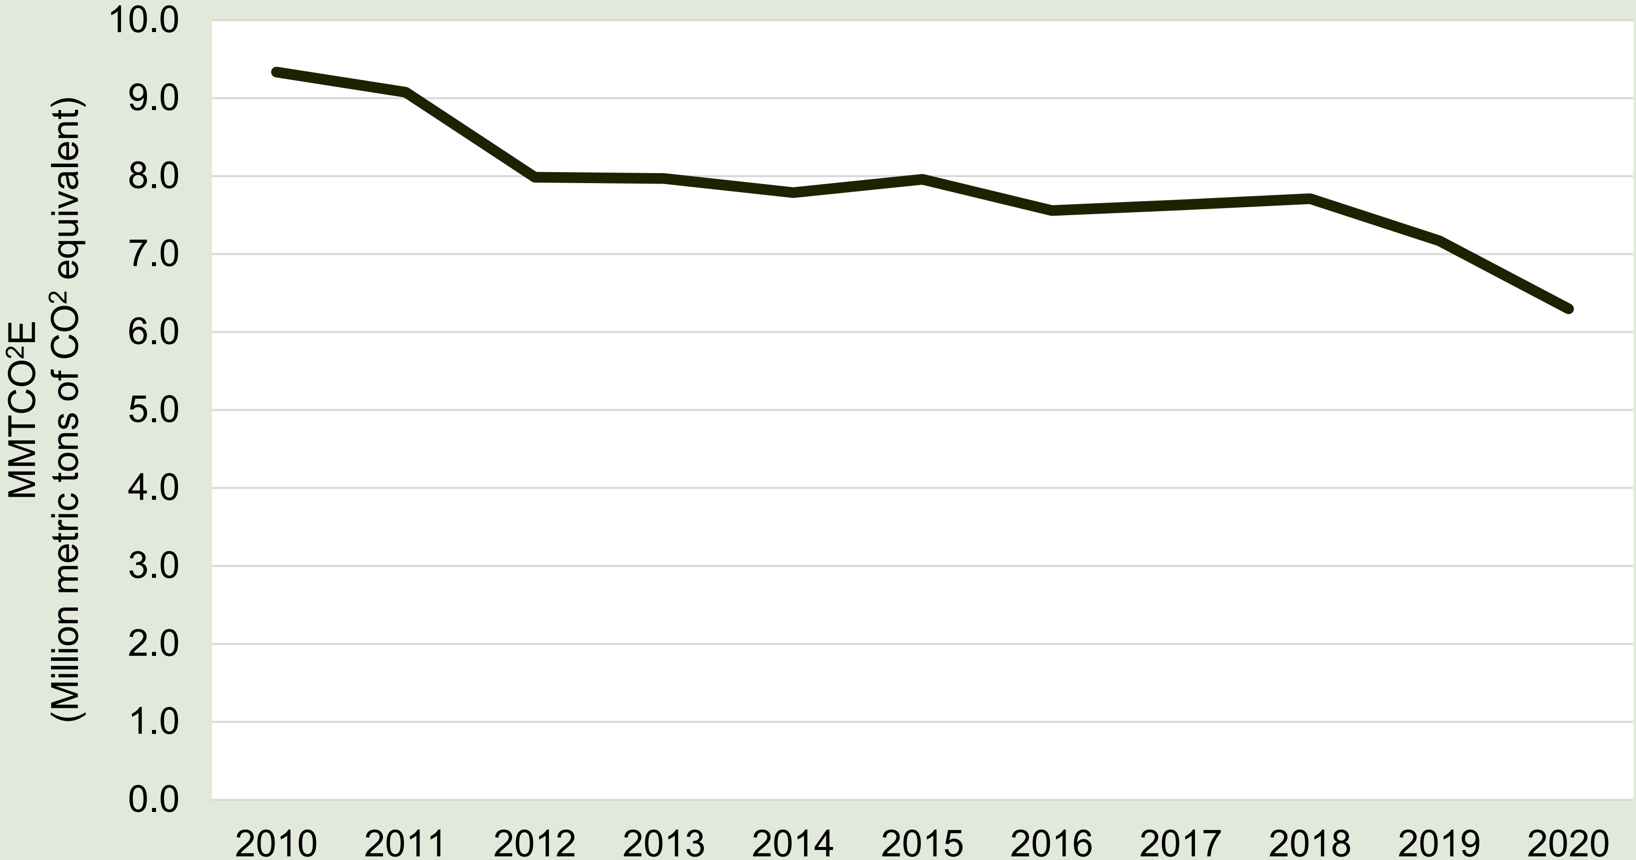
Section 7.4: Greenhouse Gas Trends

ACADIAN CONSULTING GROUP

Greenhouse Gas Emissions

Trends: Greenhouse gas total

The District of Columbia overall has seen decreases in GHG emissions, this is mostly due to switching over from coal to natural gas generation from regional power plants. Further drops in 2020 are attributed to the Covid-19 pandemic.

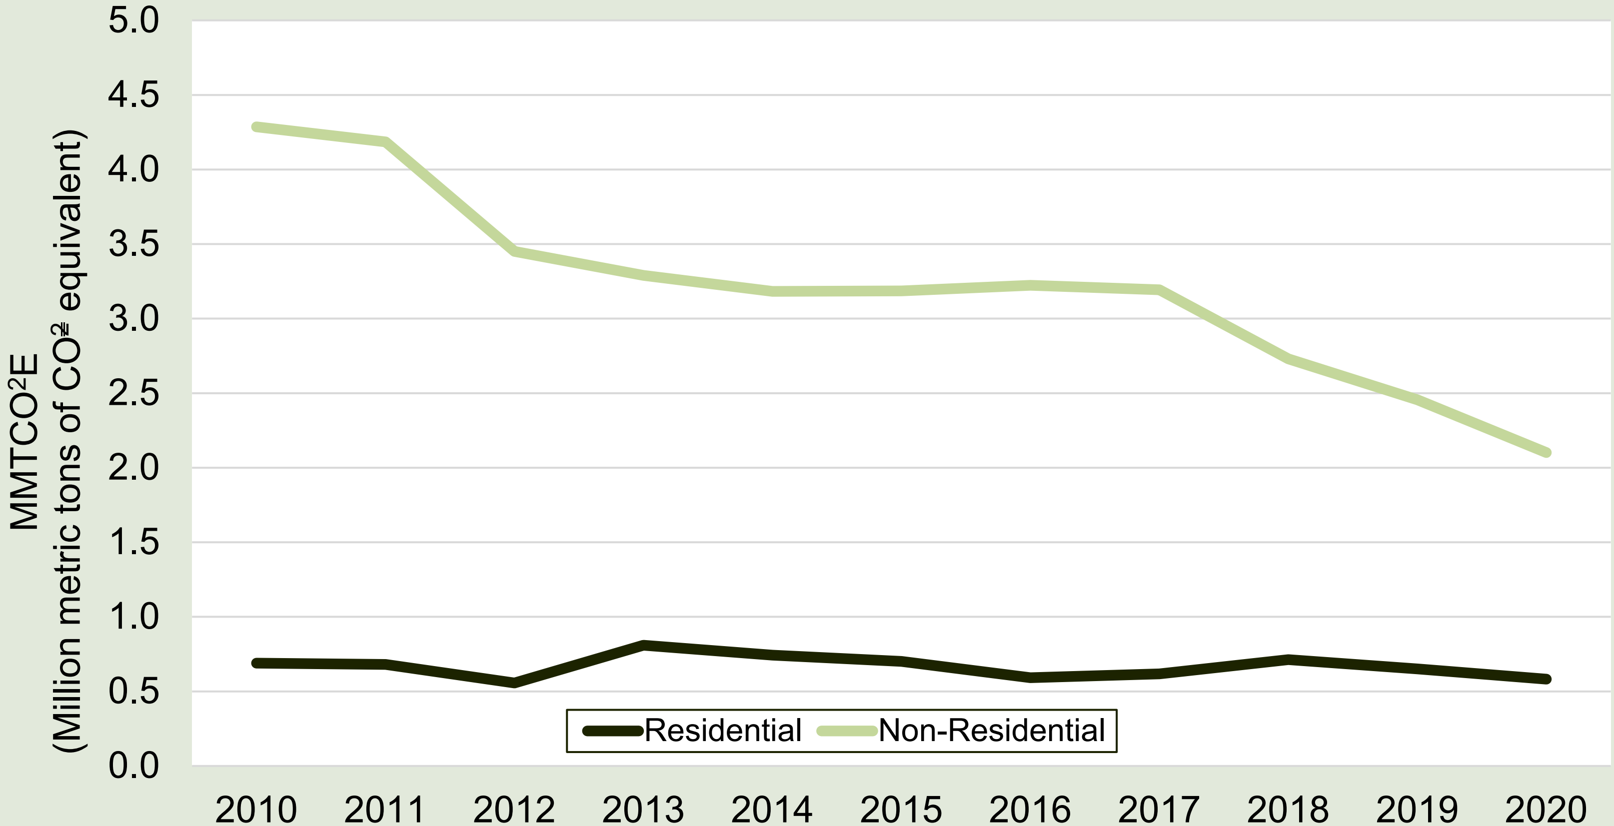


Source: DC Department of Energy & Environment

Exhibit OPC (A)-13
Formal Case No. 1176
David E. Dismukes, Ph.D.
Page 84 of 87

Trends: Building and energy electricity estimated GHG emissions.

The District of Columbia has seen very flat rates for residential electricity emissions, while non-residential emissions follow a similar trend of total GHG emissions.



Source: DC Department of Energy & Environment

Section 8: Conclusions and Recommendations

Conclusions.

There are **three major, comprehensive forms of alternative regulation**: FRPs; PBR plans; and MYRPs. To date, **no major form of alternative regulation has led to any meaningful nor measurable ratepayer benefits.** Alternative regulation **has not resulted in any sustainable nor distinctly measurable improvement in reliability or quality of service.**

Alternative regulation mechanisms have resulted in large rate increases with very few rate decreases or earning sharing opportunities.

In addition, **no measurable nor sustainable improvement in operating costs or efficiencies have arisen in any state due to alternative regulation**. In fact, most states **have seen a deterioration in capital investment discipline and huge gains in rate base due to alternative regulation**.

There is <u>not one single state adopting alternative regulation that has shown outcomes that can be held out as an unequivocal "success" for ratepayers.</u>

Commission approves Pepco's rate increase, a typical residential customer, who uses 648 kWh per month, will see a monthly bill increase of $7.56 (or 9.24% on a total bill basis).[2] In addition, Pepco requests a return on equity of 10.10%, which will allow the Company to earn a reasonable return on funds invested in the business.

Authorization of the requested rate increase will allow the Company to recover the investments it has already made in its electric distribution infrastructure and other costs necessary to operate the system. The Company has made, and continues to make, significant investments in the electric distribution system to improve reliability and customer satisfaction.[3] However, as Company Witness McGowan explains, the Company's existing electric distribution rates do not allow Pepco to fully recover the cost of providing electric distribution to its District of Columbia customers. In addition, the rate increase is also needed to finance replacement and maintenance of the Company's aging infrastructure. Furthermore, as customers use the grid differently by adding distributed resources, feeding excess generation back to the grid, or changing load patterns by charging electric vehicles at night, Pepco must make the necessary modifications to keep up with these changes.

To deliver safe and reliable service to customers, Pepco understands that it has the responsibility of improving system reliability, replacing aging infrastructure, and maintaining its electric distribution system. In doing so, Pepco requires a rate increase that will provide the Company a reasonable opportunity to earn a fair return for its District of Columbia operations.

[2] Company Witness McGowan discusses the impact of the requested rate increase on the Customer Base Rate Credit approved in Order No. 18846.

[3] Company Witness Clark testifies that the Company spent $234.8 million on capital programs in 2016 and is projected to spend $234.9 million on capital programs in 2017.

For purposes of deriving the settled-upon decrease of $24.1 million, the Settling Parties agreed, for settlement purposes only,[5] to a number of rate assumptions. For example, the NSA is based upon an overall rate of return of 7.45 percent, which includes a 9.525 percent return on equity.[6] The Settling Parties also agreed that Pepco will recalculate the negative net salvage component of its depreciation expenses for FERC Accounts 367 and 368 using a 4.60 and 6.6 percent discount rate, respectively.[7] The Settling Parties also agreed that Pepco will only include the actual cost of reliability projects that are closed to plant in service by March 31, 2018.[8] In addition, the Settling Parties agreed that Pepco will remove all Supplemental Executive Retirement Plans ("SERP") expenses previously included by the Company in its application in Formal Case No. 1150.[9]

Q. HOW DOES THE NSA PROPOSE TO INCORPORATE THE IMPACTS OF THE TCJA INTO RATES?

A. The Settling Parties made a series of agreements to define how the impacts of the TCJA will be incorporated into rates. The Settling Parties agreed to credit the Excess Deferred Income Taxes ("EDIT") created by the TCJA to rates using differing sets of fixed amortization periods to reflect (1) protected property-related EDIT, (2) non-protected property-related EDIT, and (3) non-protected, non-property-related EDIT.[10] As required by the TCJA, Pepco will use the Average Rate Assumption Method to flow back to

III. Explanation of the Need for a Rate Increase

As detailed in the testimonies of Company Witnesses Velazquez, McGowan and Verner, this case is driven by on-going investments on behalf of Pepco's customers. Specifically, Pepco has continued to invest in its system to maintain and improve reliability and to serve load growth in the District of Columbia. Pepco's revenue growth has not kept pace with the resulting growth in operating costs and rate base, and the current rates do not allow Pepco a reasonable opportunity to recover its costs and earn a fair return.[3] In spite of earning less than its Commission-authorized return on equity, Pepco has continued to initiate and implement major system improvements that have required significant amounts of capital.

Pepco's investments in its infrastructure have resulted in measurable benefits to Pepco's customers. During 2015, Pepco's customers experienced a 42% reduction in the frequency of outages, and a 33% reduction in the duration of outages (as measured by SAIFI and SAIDI, respectively) when compared to the Company's performance in 2011. Moreover, customer satisfaction with reliability has improved 14% during the same period. These investments resulting in enhanced reliability and customer satisfaction are being funded by the Company's debt and equity investors with an expectation that they will receive a reasonable return of and on their investment.

[3] At current rates, Pepco's adjusted earned return on equity ("ROE") is just 4.74%.

The Company has made, and has plans to continue to make, significant investments in the electric distribution system to maintain and improve reliability gains, continue to improve customer satisfaction, interconnect DER, and align to the District's environmental policy goals.[10] However, as Company Witness McGowan explains, the Company's existing electric distribution rates do not allow Pepco to fully recover the cost of providing electric distribution to its District of Columbia customers.

Furthermore, as customers use the grid differently by interconnecting DER, feeding excess generation back to the grid, and changing load patterns by charging electric vehicles at night, Pepco must make the modifications to the grid necessary to facilitate these changes. Pepco is excited to support the District in meeting its forward-looking policy goals and keeping pace with the fast-changing energy environment in the District of Columbia. The proposed MRP marries the traditional principles of cost of service rate design with the District's forward-looking policies, incentivizes the Company to meet the customer's needs in the face of the changing energy landscape through the proposed PIMs, and decreases the frequency, administrative burden, and costs associated with traditional rate cases. Pepco requires the proposed rate increases that will provide the Company a reasonable opportunity to earn a fair return for its District of Columbia operations.

Moreover, as Company Witness McGowan explains, the Company's proposal will allow Pepco to Maintain its investment-grade credit ratings which is vital to the financial health of Pepco and is critical to its ability to access capital markets for financing essential capital projects on

---

10 As Company Witness Clark testifies, the Company is projected to spend in excess of $600 million over the 2018-2019 time period and more than $950 million during the term of the MRP (2020-2022) on upgrades and improvements to Pepco's distribution system.

Bureau of Consumer Services
Alexis Bechtel, Director

TABLE OF CONTENTS

Executive Summary

On May 5, 2017, the Pennsylvania Public Utility Commission (Commission) initiated a study to examine home energy burdens for low-income Pennsylvanians as "a necessary first step in evaluating the affordability, cost-effectiveness, and prudence of Universal Service Programs." *Energy Affordability for Low Income Customers Order*, Docket No. M-2017-2587711 (order entered on May 5, 2017), at 1.

This staff report[1] by the Commission's Bureau of Consumer Services (BCS) and the Law Bureau tabulates 2012 to 2016 customer data related to energy burdens[2] gathered from Pennsylvania's larger natural gas distribution companies (NGDCs) and electric distribution companies (EDCs). The report also incorporates information from other states and several independent studies.[3]

This is the first comprehensive energy burden and affordability study of Pennsylvania households using customer income, billing, and payment information. While the information collected from utilities has allowed the Commission to fill in perception and presumption gaps and review trends and details that have never before been analyzed for Pennsylvania, staff has identified limitations of and inconsistencies in the reported data that impacted the scope and the extent of the analysis. In particular, the utilities that were queried for this study were unable to identify or provide income information on low-income households that did not participate in customer assistance programs (CAPs) or other universal service programs. Additionally, many of the responding utilities interpreted, tracked, and reported information differently from utility to utility and sometimes within a utility from year to year. For some years, data were not available.

It was anticipated that work at this docket would allow Commission staff to make "recommendations concerning affordable energy burdens." *Energy Affordability for Low Income Customers Order* at 5 (Ordering Paragraph #1). However, making these recommendations has proved somewhat elusive for several reasons. First, inconsistencies in utility reporting and limitations in the utility data constrain the development of a specific statement of what constitutes energy "affordability" for low-income Pennsylvanians. Further, the utilities and Commission staff were not generally privy to corresponding data for low-income customers who did not participate in a utility CAP. Second, energy efficiency and conservation can play major roles in making energy bills

[1] This report is solely the work product of staff and does not reflect the opinions of the Commission or actions that it may take in the future. The legal, policy, and procedural issues raised in this matter remain under Commission review and may be factored into a subsequent order at this or other dockets. The report will be published, and comment and reply comments periods will be established.

[2] For the purposes of this staff report, a household's energy burden is the percentage of household income dedicated to paying jurisdictional energy costs.

[3] The Commission's Consumer Services Information System (CSIS) Project at Pennsylvania State University assisted with the collation and processing of raw data and information and the review of the published studies.

more affordable. The impact of these programs on energy burden levels is not measured as part of this study. Third, the Pennsylvania Department of Human Services (DHS) administers the Commonwealth's Low-Income Home Energy Assistance Program (LIHEAP), which provides federally-funded energy assistance grants to low-income customers independent of Commonwealth- and Commission-mandated low-income benefits. As described in this report, whether low-income customers receive LIHEAP grants can have a sizable impact on customer energy burden levels.

Nevertheless, this study attempts to establish a starting point or process for identifying an affordable energy burden level for Pennsylvania's low-income population by evaluating the effectiveness of current utility CAPs. A CAP, as part of a jurisdictional energy utility's universal service and energy conservation program (universal service program), assists payment-troubled, low-income households by making their jurisdictional energy service more affordable through reduced bills and/or arrearage forgiveness. The Commission's CAP Policy Statement at 52 Pa. Code §§ 69.261-69.267 provides guidelines relative to the maximum energy burdens that low-income residential customers in customer assistance programs should be charged.[4] Currently, many low-income customers, both in CAPs and not in CAPS, have energy burdens in excess of the Commission's CAP Policy Statement guidelines.

Based on the available data, this study measures whether the various CAP payment designs are meeting universal service goals such as reducing customer debt, improving customer payment habits, reducing defaults and terminations, and reducing the number of customers in debt who are not on payment agreements. The study also examined the impact of LIHEAP grants on CAP customer energy burden levels, outlined the maximum energy burdens used by neighboring state programs, and reviewed previous third-party studies dealing with related topics. Finally, the study considers CAP cost trends and estimates the financial impact to CAP customers and non-CAP residential ratepayers if Pennsylvania were to adopt a maximum 10% energy burden.

Summarized below are staff observations related to each topic in the report. Citations have been omitted from these summaries but are included in the expanded discussion of each segment.

Energy Burden Levels for Gas and Electric Service

The study first examined the percent of household income spent on electric and gas service (*i.e.*, energy burdens) by low-income customers enrolled in CAPs and by non-CAP residential customers to determine the energy burden differences between these two groups.

[4] There is no similar guideline relative to low-income customers not enrolled in a CAP.

Even with discounted payments, CAP customers had a higher energy burden than non-CAP residential customers.[5] From 2012 to 2016, the average energy burden was 7% to 8% for NGDC CAP heating customers, 5 to 6% for EDC non-heating CAP customers, and 8 to10% for EDC CAP heating customers.[6] Residential non-CAP customers had an average annual energy burden of 4% for NGDC and EDC service during this time period, regardless of heating or non-heating status and energy type.

Customers in the 0 to 50% Federal Poverty Income Guidelines (FPIG) level, regardless of heating or non-heating status and energy type, often had energy burdens exceeding the CAP Policy Statement guidelines.

Impact of LIHEAP Grants on Energy Burden Levels

Unlike other states, Pennsylvania does not use LIHEAP grants to fund its CAPs. In Pennsylvania, LIHEAP grants issued to CAP accounts are applied as customer payments to reduce energy bills for the specific grantee-customer. Since LIHEAP is often the sole or primary source of funding for state energy assistance programs in other states, this study examined CAP accounts pre- and post-application of LIHEAP grants to determine LIHEAP's effect on energy burden levels in the Commonwealth.

The study found that LIHEAP had a measurable impact on energy burdens for CAP customers. CAP customers with incomes at or below 50% of the FPIG experienced an average energy burden decrease of approximately 5 to 6 percentage points for gas heating, 6 to 8 percentage points for electric non-heating, and approximately 7 to 9 percentage points for electric heating. CAP customers with incomes between 51 and 100% of the FPIG experienced an average energy burden decrease of approximately 2 to 3 percentage points for gas heating and 3 percentage points for electric non-heating and heating. CAP customers with incomes between 101 and 150% of the FPIG experienced an average energy burden decrease of approximately 1 to 2 percentage points for gas heating, electric non-heating, and electric heating.

Even with these decreases, however, the average energy burden for some CAP households at the 0 to 50% and 51 to 100% FPIG levels exceeded the maximum energy burden guidelines in the CAP Policy Statement.

Pre-Program Arrearages (PPAs) and In-Program Arrears

CAPs are intended to eliminate customer debt by deferring collection and payment of a CAP customer's pre-program arrearage (PPA) balance and reducing this debt with each monthly CAP payment. Full PPA forgiveness can be achieved within one to three years, depending on the utility's CAP provisions. Presumably, if CAP bills are

[5] Staff obtained data from the U.S. Census to determine average incomes for Pennsylvania non-CAP residential customers.
[6] The combined NGDC heating and EDC non-heating energy burden for CAP customers ranged between 12% and 14%.

affordable, low-income participants should gradually reduce their PPAs and accrue minimal or no new debt within the program. Staff considered the levels of PPA and in-program arrearage potential indicators of affordability within CAPs.

The data indicated that average PPAs and in-program arrears for most NGDCs showed decreasing arrearage trends, possibly due to lower natural gas costs, warmer winters, and declining CAP enrollments during this study period.

Most EDC CAP customers with in-program arrears carried an average balance of less than $200.

Since many utilities were unable to provide data for the PPA and in-program arrears balances by FPIG levels and/or by heating type, it is unclear whether customers at specific incomes (*e.g.*, at or below 50% of the FPIG) or with specific heating types carried a disproportionate share of CAP PPA or in-program arrears.

CAP enrollment eligibility varied among the utilities. Utilities that required low-income customers to be "payment troubled" (*e.g.*, had a payment arrangement in the past 12 months) to qualify for CAPs had higher average PPA balances than CAPs that did not have this restriction.

Percentage of CAP Bills Paid In-Full

If a CAP provides affordable monthly bills, the expectation was that a large percentage of participating customers would be paying their CAP bills in-full (i.e., 100% of the bill) by the due date. Staff considered payment history another possible indicator of affordability for utility CAPs.

At the 0 to 50% FPIG level, a higher percentage of NGDC CAP bills were paid in comparison to the percentage of EDC CAP bills paid in-full at the same FPIG level. Given the low cost of natural gas compared to electricity, this observation may be indicative that the bills of NGDC CAP customers were more affordable in comparison to the bills of EDC CAP customers during this five-year study period.

Payment behavior of CAP customers did not appear to have been strongly or definitively correlated to household income. EDCs reported *fewer* CAP heating customers at the 101 to 150% FPIG level paid their bills in comparison to the percentage of bills paid by customers at the 51 to 100% FPIG level. This pattern may indicate that other factors – beyond income – had an impact on whether CAP utility bills were regularly paid in full.

NGDC and EDC billing system changes and upgrades appeared to affect CAP monthly billing amounts and thus influenced whether utility bills were paid in-full.

CAP Default Exit and Termination Rates

Other indicators of affordability for CAP customers may include the rate of customers defaulting (*i.e.*, default exiting) on program requirements (*e.g.*, making full and timely payments) and termination rate for CAP customers. Presumably, CAPs with affordable monthly payments should have lower instances of customers defaulting on the programs and lower termination rates.

Given the apparent inconsistencies between how utilities defined and tracked "default exits" and CAP terminations, staff was unable to compare these data points among utilities or to confidently establish a correlation. However, differences in the CAP heating termination rates for Met-Ed and the other FirstEnergy companies suggested that other factors – besides CAP design – contributed to higher termination rates for CAP customers in Met-Ed's service territory.

Non-CAP Residential and Confirmed Low-Income Customer Debt

The final indicator of affordability reviewed was the amount of debt owed by customers on utility- or Commission-issued payment agreements and those not on agreements. When customers have difficulty paying their bills on time and accrue debt, accounts may be terminated and the debt written-off to be recovered through base rates. Debt that is on agreement is considered active and less at risk for write-off. Debt that is not on agreement is considered a higher risk for write-off.

The number of NGDC and EDC confirmed low-income customers in debt to their utility who were not on payment agreements had declined from 2012 to 2016. This may indicate that utilities were having greater success in either enrolling/maintaining low-income customers into CAPs or in establishing payment agreements.[7]

Review of Other State Programs and Relevant Studies

Pennsylvania's maximum energy burdens as articulated in the CAP Policy Statement are higher than maximum energy burdens used by neighboring states. Ohio's utility payment assistance program has a maximum energy burden of 10%. The New York and New Jersey utility payment assistance programs both have a maximum energy burden level of 6%.

Staff reviewed multiple independent studies that dealt with topics similar to those addressed in this study. Insights from these studies include:

- If the cost of all sources of household energy are counted – not just natural gas and electric – Pennsylvania households with incomes at or below 150% of the FPIG experience some of the highest energy burdens in the country. Pennsylvania residents with incomes at or below 50% of the FPIG had energy burden levels at

[7] However, these assumptions cannot be confirmed from available data.

30% or higher for four of the five years of this study. This suggests that households that use non-electric heating (*e.g.*, propane, oil) may have higher energy burden levels than those reflected in this study.

- Although nearly eight-in-ten Pennsylvanians live in urban areas,[8] households in rural areas may experience the highest energy burden levels due to poor housing stock. Focusing energy-efficient education and weatherization services can help to reduce the energy burden disparity in these areas and help make CAPs more effective.
- Payment behavior may not reflect affordability. Customers may neglect other household expenses to pay their utility bill each month;
- Not every household in poverty is payment-troubled;
- Factors other than income play a role in determining the effectiveness of an assistance program; and
- Customers that enter a payment assistance program with lower PPAs are more likely to improve their payment behavior than customers with higher PPAs.

CAP Costs and Forecasts

Based on information submitted by NGDCs and EDCs in support of USECPs covering the period after 2016, NDGC and EDC CAP costs are projected to increase annually through 2021 despite an industry drop in CAP expenditures from 2012-2016. The overall average costs per non-CAP residential customer are also projected to increase through 2021, varying among the utilities and with CAP enrollments levels. EDC customers could experience the largest increase, with average annual CAP costs recovered from non-CAP residential customers projected to increase by approximately $20 from 2017 to 2021.

Based on an energy burden model developed by Commission staff for this Report, staff estimated the cost of establishing a 10% maximum energy burden level for CAPs, which parallels Ohio's maximum energy burden level. Based on 2012 to 2016 average CAP bills and income levels, the total amount of additional discounts (*i.e.*, CAP credits) that would have been needed to establish maximum energy burdens of 6% for gas heating, 4% for electric non-heating, and 10% for electric heating would be approximately $102 million per year, not accounting for inflation. This amount breaks down to approximately $32 million for gas heating, $62 million for electric non-heating, and $9 million for electric heating. Such a change would have resulted in an average annual increase of $14.52 to non-CAP residential ratepayers' gas and electric bills. Average increases would vary among the utilities.

The energy burden model developed by staff for this Report does not factor in all variables and specifically does not take into consideration (1) any possible reductions in CAP costs if some CAP customers are required to pay more under a new energy burden

[8] Pennsylvania State Data Center, Penn State Harrisburg. (October 2012). Pennsylvania's Urban and Rural Population. Retrieved from http://pasdc.hbg.psu.edu/sdc/pasdc_files/researchbriefs/Urban_Rural_SF1_RB.pdf.

level; (2) whether rate discount pricing (rather than, *e.g.*, percent of income pricing) might be better for some CAP customers or reduce overall CAP costs; (3) CAP costs borne by PGW's non-residential ratepayers; (4) individual utility CAP credit limits; (5) system/administrative costs associated with adopting new energy burdens; and (6) factors specific to each utility.

Study Limitations

There have been changes in utility CAPs and other universal service programs since the data reviewed in this study were collected. Such program changes are on-going. More current data reflecting these changes may have an impact on the observations drawn in this study. Further inspection of future data may substantiate trends as well as identify the aspects of CAPs that appear to work well or that produce better customer outcomes. Collection of valid data that can be consistently compared across income levels, among utilities, and over time would increase the reliability of projections and allow better evaluations of the success of CAPs.

I. Introduction

According to the 2012-2016 American Community Survey (ACS) data, Pennsylvania had a population of approximately 12.8 million and approximately 5 million housing units.[9] Almost 38% of Pennsylvania residents were either elderly (age 65 or over) or minors (under 18). Over 70% of Pennsylvania households heat with either natural gas or electricity (51% of heat with natural gas and 22% heat with electricity).[10] Over one-third of Pennsylvania households experience some level of poverty.[11] Approximately 8% of Pennsylvania's households reported incomes below 50% of the FPIG; 17% reported incomes below 100%; 27% reported incomes below 150%, and 37% had incomes below 200%, cumulatively.[12]

Universal Service Programs in Pennsylvania

The Commission's leadership in addressing the home energy needs of low-income households in Pennsylvania began as early as 1984 when it commenced *Recommendations for Dealing with Payment Troubled Customers* at Docket No. M-840403. As a result of that proceeding, energy utilities in Pennsylvania began implementing low-income usage reduction programs (LIURPs) and contemplating how to address the arrearages of low-income customers.

In 1992, with the continued accumulation of arrearages and uncollectable debt by low-income utility customers, the Commission adopted a policy statement at 52 Pa. Code §§ 69.261-69.267 that established guidelines for major electric and natural gas utilities to voluntarily implement pilot CAPs. The purpose of a CAP is two-fold: to help make utility services more affordable for low-income, payment-troubled individuals and to reduce the costs of a utility's uncollectible amounts. *Investigation of Uncollectible Balances*, Docket No. I-900002, at 115 to 118. Low-income, payment-troubled customers are defined as residential utility customers whose annual household gross income is at or below 150% of the FPIG and who have failed to maintain one or more payment arrangements.[13] 52 Pa. Code §§ 54.72 and 62.2.

The CAP Policy Statement, which was subsequently amended, in part, in 1999, provides guidelines on the design and operation of CAPs, including establishing guidance on maximum energy burden ranges that low-income customers could be expected to pay in exchange for continued utility services. The 1992 CAP Policy Statement

[10] 2012-2016 ACS 5-Year Estimates.
[11] Approximately 15% of Pennsylvania residents were age 65 and over and 23% were under the age of 18. 2012-2016 ACS 5-Year Estimates.
[12] *See* Appendix 1 for demographic profiles for each NGDC and EDC service territory.
[13] The requirement of a missed payment arrangement has been somewhat eased over the years by Commission orders regarding individual utility universal service programs.

recommended that a CAP customer's combined jurisdictional natural gas and electric energy burden should not exceed 15%. The 1999 CAP Policy Statement amendment increased the maximum household energy burden to 17%. Table 1-1 below indicates the energy burden levels based on the FPIG and the nature of the energy usage in the household from Section 69.625 in the CAP Policy Statement.

Table 1-1
CAP Policy Statement Maximum Energy Burden Levels[14]

Utility Service	0-50% FPIG	51-100% FPIG	101-150% FPIG
Non-Heat Electric	2-5%	4-6%	6-7%
Gas Heat	5-8%	7-10%	9-10%
Electric Heat	7-13%	11-16%	15-17%

The Competition Acts

In 1997 and 1999, respectively, the Electricity Generation Customer Choice and Competition Act (Electric Competition Act), 66 Pa. C.S. §§ 2801-2812 and the Natural Gas Choice and Competition Act (Gas Competition Act), 66 Pa. C.S. §§ 2201-2212, were adopted. (Collectively, Competition Acts.) The primary purpose of the Competition Acts was to introduce competition into the retail electric and natural gas markets by establishing standards and procedures for the restructuring of the electric and natural gas utility industries. The Competition Acts also included several provisions relating to universal service programs for low-income customers in the Commonwealth. The Competition Acts require the Commission to continue, at a minimum, the policies, practices, and services that were in existence as of the effective date of the laws. 66 Pa. C.S. §§ 2203(7) and 2802(10).

The Competition Acts define "universal service and energy conservation" as the policies, practices, and services that help low-income customers maintain utility service. Although the universal service provisions of the Competition Acts tie the affordability of electric and natural gas service to a customer's ability to maintain utility service, the Competition Acts do not specifically define the term "affordable" as it relates to the provision of retail electric and natural gas services to customers.[15]

---

[14] 52 Pa. Code § 69.265(2)(i)(A-C).
[15] Section 2202 defines "universal service and energy conservation" as the "[p]olicies, practices and services that help residential low-income retail gas customers and other residential retail gas customers experiencing temporary emergencies, as defined by the [C]ommission, to maintain natural gas supply and distribution services. The term includes retail gas [CAPs], termination of service protections and consumer protection policies and services that help residential low-income customers and other residential customers experiencing temporary emergencies to reduce or manage energy consumption in a cost-effective manner, such as [LIURPs] and consumer education." Section 2803 defines universal service and energy conservation as the "[p]olicies, protections and services that help low-income customers to maintain electric service. The term includes [CAPs], termination of service protection and policies and services that help low-

The Commission is tasked with ensuring that utilities administer universal programs in a cost-effective manner and that services are appropriately funded and available in each utility distribution territory. 66 Pa. C.S. §§ 2203(8) and 2804(9). In the exercise of this authority, the Commission balances the interests of customers who benefit from the programs with the interests of the residential customers who pay for the programs. *See Final Investigatory Order on CAPs: Funding Levels and Cost Recovery Mechanisms*, Docket No. M-00051923 (Dec. 18, 2006), (*Final CAP Investigatory Order*), at 6-7.[16]

Universal Service Programs

Utility universal service programs include CAP, LIURP, Customer Assistance Referral and Evaluation Program (CARES), and Hardship Funds. Of particular relevance to this study and report are the CAPs which are administered individually by the major EDCs and NGDCs. CAPs, which vary in design by utility, provide an alternative to traditional collection methods for low-income, payment-troubled customers. Customers who enroll in a CAP agree to make monthly payments in exchange for continued utility services and debt forgiveness. Those monthly payments, which may be set at an amount less than the customer's current bill based on usage at tariff rates, are generally based on factors such as household size and gross income of the household and may include an add-on amount to help offset the customer's pre-program arrearages (PPAs), if relevant. EDCs and NGDCs may call their respective CAPs by different names (*e.g.*, PPL refers to its CAP as OnTrack, PGW refers to its CAP as the Customer Responsibility Program or CRP). For the purposes of this report, staff will collectively refer to all utility customer assistance programs as CAPs.

Energy Affordability for Low-Income Customers Study

On May 5, 2017, at Docket No. M-2017-2587711, the Commission initiated a study to evaluate residential energy burdens for electric and gas service in Pennsylvania

---

income customers to reduce or manage energy consumption in a cost-effective manner, such as [LIURPs], application of renewable resources and consumer education."

[16] The proceeding at Docket No. M-00051923 was closed December 18, 2006, and staff was directed to revise the CAP Policy Statement (OP 1) and to initiate a rulemaking regarding funding and design of CAPs (OP 2). Two proceedings were opened: *Proposed Revision to CAP Policy Statement*, Docket No, M-00072036 (order entered September 5, 2007), and *Proposed Rulemaking relating to Universal Service and Energy Conservation Reporting Requirements*, Docket No, L-00070186 (order entered September 4, 2007). These dockets were closed by Commission order entered May 10, 2012, due, in part, to "changes to the LIHEAP policy and the initiation of a stakeholder process studying the treatment of universal service customers in an enhanced competitive retail electricity market. . . . [*See Investigation of Pennsylvania's Retail Electricity Market*, Docket No. I-2011-2237952.] . . . A new rulemaking and amended policy statement will be initiated in the future after these issues have been resolved and the stakeholder process completed." May 10, 2012 Order at-12-14,

and to determine what may constitute an affordable energy burden for Pennsylvania's low-income households. May 5, 2017 Order. Despite the programs and services designed to bridge the energy affordability gap[17] in Pennsylvania, the Commission routinely receives complaints from customers enrolled in CAPs who are failing to or are unable to keep up with payments, accumulating in-program arrears, facing loss of program eligibility, and risking service termination. *See, e.g., Knapp v. Penelec*, Docket No. C-2015-2511723 (Order entered October 27, 2016). This payment, assistance, and arrearage cycle is a recurring issue for many low-income customers in the state.

According to some sources, households falling below 50% of the FPIG are billed an average of 30% of their income for home energy costs.[18] However, only approximately 30% of eligible Pennsylvania households are enrolled in a CAP.[19] Given these realities, the Commission concluded that the necessary first step to evaluate the affordability, cost-effectiveness, and prudence of universal service programs would be to undertake an energy affordability study. The Commission also recognized its obligation to balance the costs[20] and benefits of universal service programs as potential changes to affordability standards will inevitably require an examination of overall program funding. May 5, 2017 Order at 3-4.

While other fuel sources[21] are available and used by households in Pennsylvania, for purposes of this study the Commission is exclusively examining the affordability of jurisdictional natural gas and electric services to low-income customers in Pennsylvania. The original intent of this study was to examine energy affordability for low-income customers both inside and outside of CAPs. However, NGDCs and EDCs could not provide income information and other data for customers who were not participating in CAPs or other universal service programs. Further, absent enrollment in a CAP, even a confirmed low-income residential customer is required to pay the full tariff rate for

---

[17] Fisher, Sheehan, & Colton, cited and discussed in greater detail below, use "affordability gap" to refer to the difference between *actual home energy bills* and *affordable home energy bills*.

[18] Fisher, Sheehan, & Colton. *The Home Energy Affordability Gap 2015: Pennsylvania* (Public Finance and General Economics, 2nd Ser. 2016), at 1. These studies are based on jurisdictional and deliverable energy sources.

[19] 2012-2016 Reports on Universal Service Programs & Collections Performance.
http://www.puc.state.pa.us/filing_resources/universal_service_reports.aspx
http://www.puc.state.pa.us/filing_resources/universal_service_reports.aspx

[20] The May 5, 2017 Order noted that, based on a review of the Commission's Reports on Universal Service Programs & Collections Performance for the years 2001 through 2015, total gross CAP costs for EDCs have increased by approximately 177% between 2001 and 2015 (inflation adjusted), from $68.25 million to $189 million (expressed in 2001 dollars). Total gross CAP costs for NGDCs distribution companies have increased by approximately 270% between 2002 and 2015 (inflation adjusted), from $22.6 million to $83.6 million (expressed in 2002 dollars). Additionally, during the 2001/2002 to 2015 timeframe, the numbers of estimated low-income EDC and NGDC customers have increased by 80% and 104%, respectively.

[21] Also, not included in this study are customers of such energy providers as small jurisdictional NGDCs and EDCs, rural electric cooperatives, municipal authorities, and municipalities providing energy services to customers outside the municipal boundaries.

jurisdictional energy service. As a result, the staff analysis focuses primarily on low-income customers enrolled in large-utility CAPs.

Specifically, the overarching objectives of this study are to:

1. Identify the average energy burden of low-income customers enrolled in CAPs compared to the average energy burden of all other residential customers in Pennsylvania and the impact of LIHEAP grants on CAP energy burden levels;

2. Ascertain and analyze trends and indicators of energy affordability in Pennsylvania CAPs, including PPAs (*i.e.*, pre-CAP arrearages) and in-program CAP arrears, the percentage of CAP bills paid in-full, and CAP default/termination rates;

3. Determine trends in residential/low-income debt and CAP costs for EDCs and NGDCs and identify the projected impacts of adjusting the household energy burden in the Commonwealth; and

4. Compare and contrast the average energy burden of low-income residents in Pennsylvania with the energy burden of customers of neighboring states.

Staff used the Commission's CSIS Project at Penn State University to collect and collate the results of the utility responses and the state surveys and to review independent studies that may provide further insight into energy affordability issues. The analyses and observations in this report are solely the work product of staff[22] and do not reflect the opinions of the Commission. Nor is this report an indication of any action the Commission may take in the future.

[22] This document is the collective work product of BCS and the Law Bureau.

II. Methodology

By Secretarial Letter dated October 16, 2017, the Commission notified the major jurisdictional energy distribution companies of its intent to conduct an energy affordability study and requested specific information from the eight major NGDCs and seven major EDCs for the years 2012-2016. The NGDCs and EDCs that reported data to the Commission include the following:

> **Natural Gas**: Columbia Gas of Pennsylvania (Columbia), PECO Energy Co. (PECO Gas), National Fuel Gas Distribution Corp. (NFG), Peoples Natural Gas Co. (Peoples), Peoples-Equitable Division (Peoples Equitable), Philadelphia Gas Works (PGW), UGI Utilities Inc.– Gas (UGI Gas) and UGI Penn Natural Gas (UGI PNG).[23]
>
> **Electric**: Duquesne Light Co. (Duquesne), Metropolitan Edison Co. (Met-Ed), PECO Energy Co. (PECO Electric), Pennsylvania Electric Co. (Penelec), Pennsylvania Power Co. (Penn Power), PPL Electric Utilities Corp. (PPL), and West Penn Power Co. (West Penn).

The Commission's data request asked for the following information, broken down by customer type (residential, confirmed low-income [CLI], CAP), by heating type, and by poverty level from each NGDC and EDC, consistent with universal service and collections reporting (USR) requirements[24]:

- Number of monthly bills issued
- Amount (in dollars) of monthly bills issued
- Number of monthly bills paid in full
- Amount (in dollars) of monthly bills paid in full
- Number of account terminations
- Number of account reconnections
- Energy Burden Levels for LIHEAP recipients
- Energy Burden Levels for non-LIHEAP recipients
- Number of CAP Accounts with Pre-Program Arrears

---

[23] By Order entered September 20, 2018, the Commission approved a Joint Petition for Approval of Settlement in *Joint Application of UGI Utilities, Inc., UGI Penn Natural Gas, Inc., and UGI Central Penn Gas, Inc. for Approval of Merger*, Docket Nos. A-2018-3000381, A-2018-3000382, & A-2018-3000383. By Secretarial Letter at those dockets, the Commission approved tariff supplements, effective October 1, 2018, that reflect post-merger name changes due to the adoption by UGI Utilities, Inc. of UGI Penn Natural Gas, Inc.'s and UGI Central Penn Gas, Inc.'s existing tariffs and their application within new service and rate districts of UGI Utilities, Inc. corresponding to their existing service territories as UGI North and UGI Central, respectively, and the adoption by UGI Utilities, Inc. of its existing tariff to be applied to a new UGI South service and rate district. For the purposes of this study, which references data for a time period prior to the merger, the UGI companies were treated as separate NGDCs.

[24] Pursuant to 52 Pa. Code §§ 54.71-54.78 (electric) and §§ 62.1-62.8 (natural gas).

- Amount (in dollars) of Pre-Program Arrears
- Number of CAP Accounts with In-Program Arrears
- Amount (in dollars) of In-Program Arrears
- Number of CAP and Confirmed Low-Income Accounts
- Annual average income of CAP and Confirmed Low-Income accounts
- Number of accounts in arrears on an agreement
- Number of accounts in arrears not on an agreement
- Amount of arrears (in dollars) for accounts on an agreement
- Amount of arrears (in dollars) for accounts not on an agreement

When an analysis in this report refers to an "average" for multiple utilities, the average is a weighted average to compensate for the differences in size among the utilities.

Data Limitations

Staff identified inconsistencies and limitations in the reported data that impacted the analysis. Reasons for data variations included policy and procedure changes implemented by the utilities during the five-year time frame, specific enhancements to their systems, changes to their low-income programs, and/or mergers/acquisitions. Upon review of the data submitted, staff also found many utilities interpreted, tracked, and reported information differently.

At the onset of the study, the Commission initially requested the above data be categorized by CAP, CLI, and non-CAP residential accounts. Although the utilities responded to this request, staff questioned the validity and consistency of some of the reported numbers of CLI accounts; thus, the data used in this report do not always differentiate between CLI and non-CAP residential.

Furthermore, there is marked variability among the utilities in how they determine and verify the income status of their customers. For example, some utilities allow customers to "self-certify" their income designation while others require documentation from the customer to verify income status. As a result, staff used current U.S. Census data, when appropriate, to describe any relevant demographics of a utility's service area as opposed to the low-income account information submitted by the utilities.

III. Energy Burden Levels for Gas and Electric Service

Objective

Examining the percent of household income spent on electric and gas service (*i.e.*, energy burdens) by low-income customers enrolled in CAPs and by non-CAP residential customers to determine the energy burden differences between these two groups.

Background[25]

For the purposes of this segment, staff intended to compare three groups of residential customers: CAP households, residential non-CAP households, and CLI households. While all three groups of residential customers comprise the Residential Class of customers, CAP households are tracked separately as a group. CLI households are a subset of the non-CAP residential household group. The utilities reported that they do not possess income information for most CLI customers.[26] Thus, this segment will only compare CAP energy burdens to non-CAP residential energy burdens.

Staff considered the following components:

- The average energy burden for households for electric and gas service;
- Individual utility service type (electric heating, electric non-heating, and natural gas heating);
- FPIG level; and
- Status as residential non-CAP or CAP customer for the past five years.

Additionally, utilities use a variety of payment approaches to structure their CAP programs, consistent with the CAP Policy Statement guidelines. Utilities charge different amounts, offer various percentage discounts or billing options, and can have differing minimum payment requirements. Table 3-1 below shows each utility's CAP payment method and any applicable minimum payments for both heating and non-heating accounts during the study.

[25] *See also* VIII. Residential and Confirmed Low-Income Customer Debt for a discussion of CLI customers.
[26] CLI customers are often identified when they assign a LIHEAP grant to the utility. Receipt of LIHEAP confirms the customer has income at or below 150% of the FPIG, but it does not disclose the household's gross income, so energy burdens at the three FPIG levels cannot be calculated for comparison.

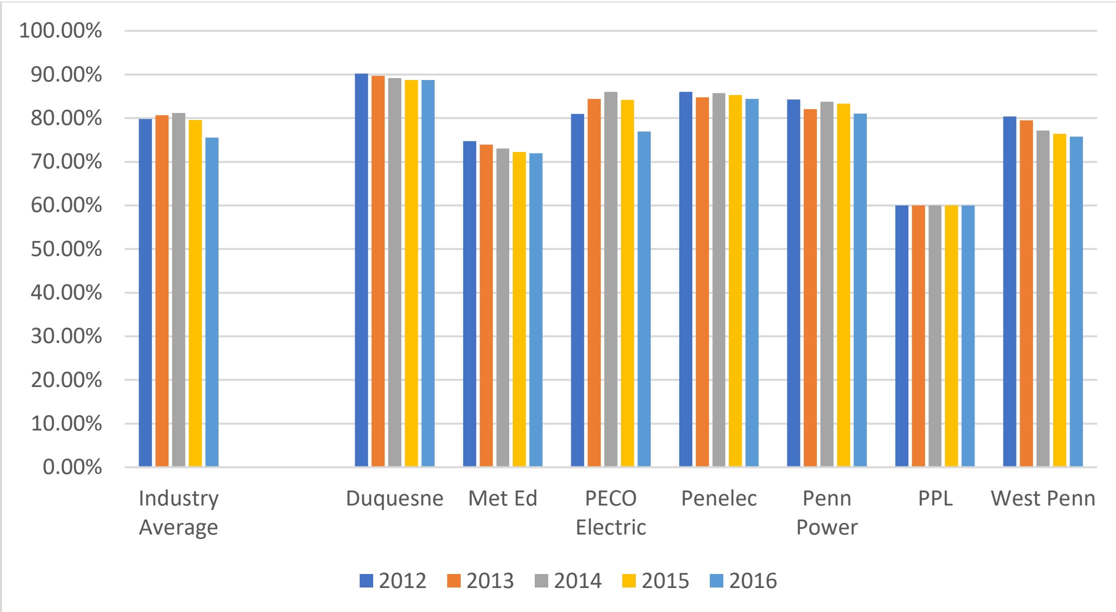
Table 3-1
CAP Billing Methods by Utility

Utility	CAP Billing Method	Minimum Payments
Duquesne	*Percentage of Budget Billing* 30% to 85% of Budget Billing	**Heat:** \$40 **Non-Heat:** \$15
FE Companies: Met-Ed, Penelec, and Penn Power West Penn (2016)	*Percent of Income and Fixed Annual Credits* Annual credits are calculated based on customer paying 3% of income for non-heat electric and 9% for electric heat. FE Companies provide 1/12th of annual credits each month.	**Heat:** \$45 **Non-Heat:** \$12
West Penn (formerly Allegheny Power) West Penn (2012-2015)	*Percentage of Income Payment Plan* Subsidy credits are calculated based on total gross household income, primary heat source, and energy burden. 1. Either 13%, 16%, or 17% of income for Electric Heat 2. Either 8%, 12%, or 14% of income for Water Heat 3. Either 5%, 6%, or 7% for Baseload Heat *(i.e.*, electric non-heating)	**Electric Heat:** \$50 **Water Heat:** \$30 **Baseload Heat:** \$25
PECO Electric*	*Rate Discount* Between 3-93% discount (dependent upon the household's FPIG level)	**Heat:** \$30 **Non-Heat:** \$12
PPL	*Percentage of Budget Billing* 3 options based on customer ability to pay: 1. Minimum Payment (budget bill - maximum monthly CAP credit) 2. 50% to 80% of Budget Billing 3. Agency Selected (% of budget bill plus discounts)	**Heat:** \$30 **Non-Heat:** \$12
Columbia	*Percent of Income, Budget Billing, or Average Payment* 3 options based on customer ability to pay: 1. 7% or 9% of income 2. Average payment 3. 50% of budget billing	**Heat:** \$25
PECO Gas*	*Rate Discount* Between 14-79% (dependent upon the Household's FPIG level)	**Heat:** \$25
Peoples	*Percentage of Income* 8% to 10% of income OR budget billing, whichever is lower	**Heat:** \$21
Peoples-Equitable	*Percentage of Income* 8% to 10% of income	**Heat:** \$39
NFG	*Rate Discount* 10-40% discount off budget billing	**Heat:** \$12
PGW	*Percentage of Income* 8% to 10% of income	**Heat:** \$25
UGI Gas and UGI PNG	*Percentage of Income* 7% to 9% of income OR average bill, whichever is lower	**Heat:** \$25

*PECO implemented a fixed credit methodology as part of its gas and electric CAP on October 1, 2016.

Table 3-1 above does not delineate the utilities that that add CAP Plus[27] and/or monthly PPA co-payment amounts[28] to the CAP customer bills.

Table 3-2
Percent of EDC CAP Bills Rendered to Non-Heating Customers



Another consideration to note is that Pennsylvania EDCs have a higher percentage of non-heating accounts in CAP than heating accounts. As seen in Table 3-2, based on the PA industry average, over 75% of EDC CAP bills issued were for non-heating accounts. *See* Appendix 5.D *for EDCs Number of CAP Bills Paid*. Thus, affordability issues involving electric non-heating accounts impact the majority of EDC CAP customers.

Methodology

To calculate the energy burden levels for non-CAP residential and CAP customers for the years 2012 to 2016, staff obtained data from the utilities and information from the U.S. Census to determine average bills and average incomes for both sets of customers. The average annual tariff rate, usage, and median income was used to determine the

[27] A CAP Plus payment is intended to help offset program expenses for all residential customers who pay for CAPs. Utilities that use CAP Plus typically calculate the monthly charge on an annual basis contingent on the amount of LIHEAP Cash grants they were assigned by their CAP customers in the prior year. At the time of this study, PPL, Columbia Gas, and Peoples added CAP Plus amounts to CAP bills.

[28] Some NGDCs and EDCs charge a monthly PPA co-payment amount to their CAP customers. During the time of this study, Columbia Gas, Peoples, Peoples-Equitable, and PGW each added a $5 co-payment to the monthly CAP bill for customers that had PPAs. Until 2018, PPL charged its $5 monthly PPA co-payment even if a customer had received full PPA forgiveness.

average energy burden levels for non-CAP residential customers. The average annual CAP bill amount and the average annual CAP income were used to determine the average energy burden levels for CAP customers.

Data Limitations

Customers who enroll in utility CAPs with zero income (zero-income customers) may inflate the average energy burdens levels, particularly for the analysis of customers with incomes at or below 50% of the FPIG. Utilities require customers that report zero income to pay the utility's CAP minimum payment amount. Thus, it is not mathematically possible for zero-income customers to receive bills below the maximum energy burden guidelines in the CAP Policy Statement because any billed amount will exceed 100% of their household income. There is some question regarding whether or not the utilities treated the zero-income customers consistently when reporting data for this study.

PPL reported system issues that required it to reconstruct all data prior to 2016 for several of the requested data points. Thus, all PPL data for the energy burden calculations in 2012 to 2015 should be considered estimates.

PECO originally reported combined data for all three customer types, electric heating, electric non-heating and gas heating. PECO was instructed to separate electric from gas but had to apply an allocation percentage to separate the dual-enrolled customers. PECO used actual 2016 data, but the 2012 to 2015 data had to be estimated.

NFG could not provide its data broken down by FPIG level, so staff did not include NFG in the analysis of NGDC average energy burdens at different FPIG levels, and only included NFG in the aggregate analysis.

As noted above, the utilities do not have income levels for the CLI customers so the CLI aspect of this study has been eliminated.

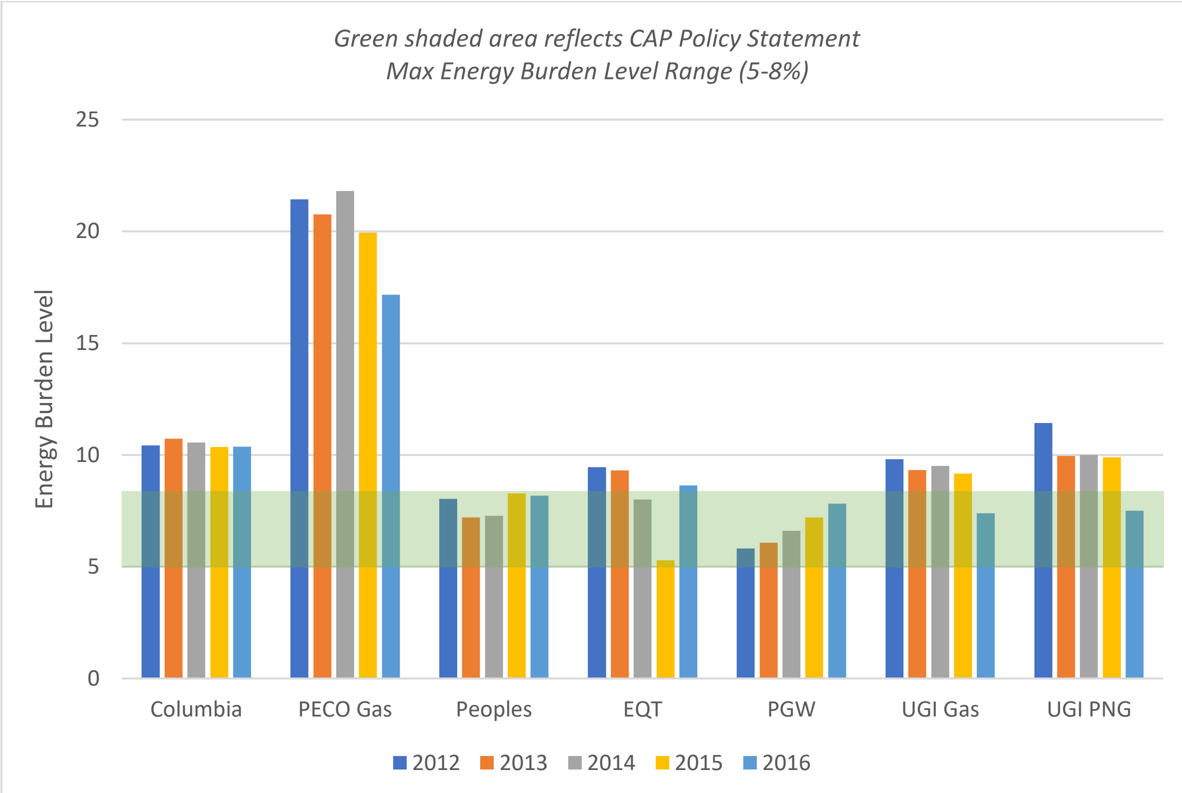
Analysis

Non-CAP Residential NGDC and EDC Customers

The non-CAP residential data show that the average energy burden for residential customers was approximately 4% for combined gas heating and electric non-heating (*i.e.*, 2% for each) and 4% for electric heating. These data can be found in Appendix 1.A: *Non-CAP Residential NGDC and EDC Average Energy Burdens*. For the residential categories, the averages did not vary widely throughout the years of the study or among the utilities and remained relatively consistent for the non-CAP residential customers.

NGDC CAP Customers[29]

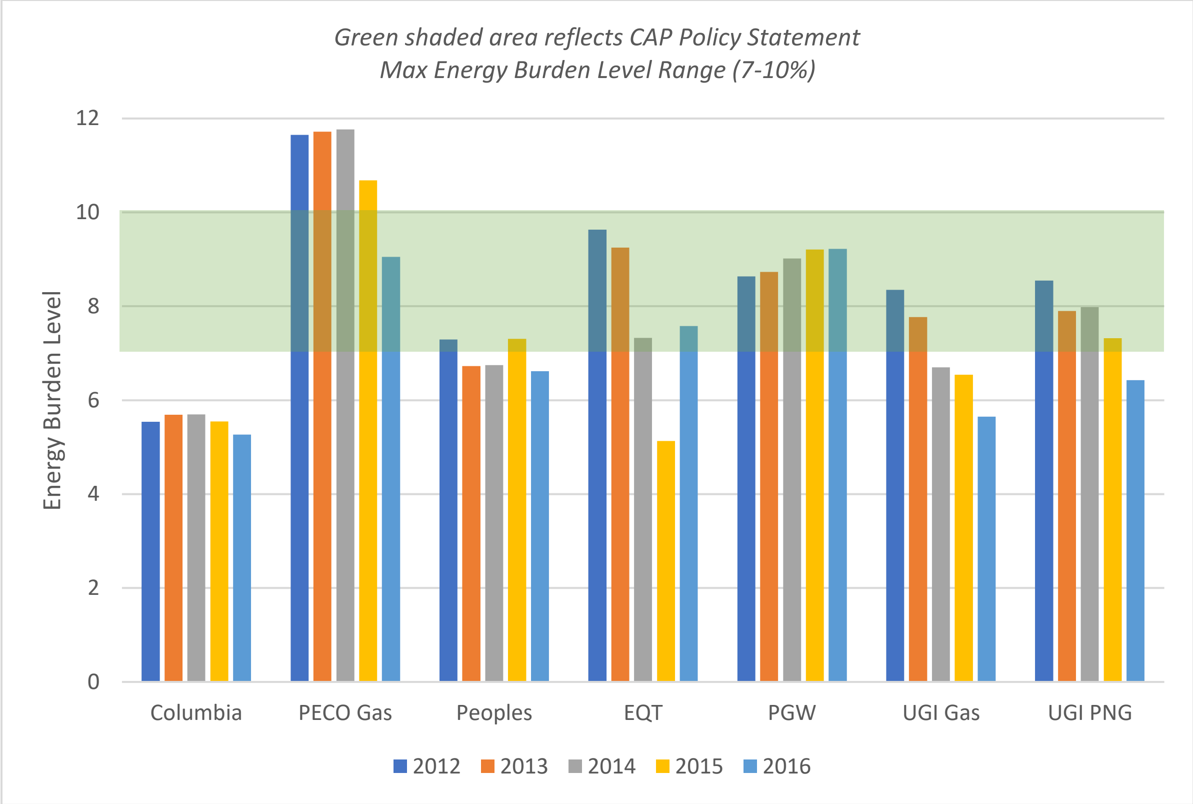
Table 3-3
NGDC CAP Energy Burden Levels for Heating Customers at 0-50% of FPIG, 2012-2016



NGDC CAP customers in the 0-50% FPIG level had the highest reported energy burdens. CAP customers at this income level from Columbia, Peoples Equitable, PECO Gas, UGI Gas, and UGI PNG had energy burdens that exceeded the guidelines in the CAP Policy Statement. PECO Gas' energy burdens for customers at this income level ranged from 17% to 22% over the five years of this study. Columbia's percentages remained in the 10% range throughout this study. Peoples Natural Gas' energy burdens were also relatively consistent, but lower at the 7 to 8% range. The remaining NGDCs had energy burdens that varied from year to year but generally stayed within a few percentage points: Peoples Equitable ranged from 5-9%, UGI PNG from 7 to 11%, UGI Gas from 7 to 10%, and PGW from 6 to 8%. This pattern is illustrated in Table 3-3 above.

29 *See* Appendix 2.B: *CAP Industry Average NGDC and EDC Energy Burdens.*

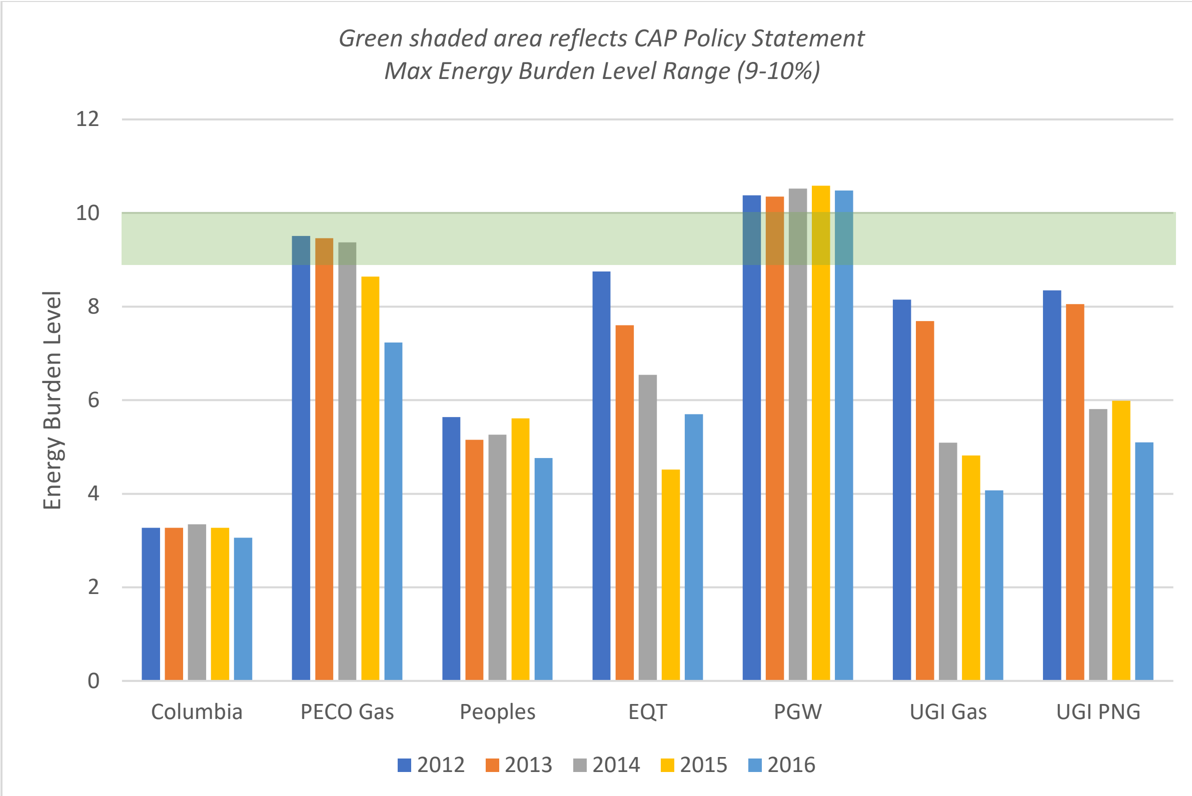
Table 3-4
NGDC CAP Energy Burden Levels for Heating Customers at 51-100% of FPIG, 2012-2016



As seen in Table 3-4, on average, NGDC CAP customers with incomes in the 51 to 100% FPIG level had energy burdens that fell within or below the CAP Policy Statement range of 7 to 10%. PECO Gas, however, had the highest energy burdens in the category with three out of five years above the CAP Policy Statement guidelines. Overall, the PECO Gas energy burdens were between 9 and 12% which is above the range in the CAP Policy Statement guidelines and replicates the trend from the 0 to 50% FPIG level. PECO's lowest energy burden in 2016, was within the range in the CAP Policy Statement guidelines.[30] Columbia's energy burdens fell well below the range and were consistently less than 6%. Peoples Gas' energy burdens averaged 6 to 7%; PGW's energy burdens averaged 8 to 9%. Peoples Equitable and both UGI utilities also fell within the CAP Policy Statement guidelines for this income level.

[30] PECO switched from a rate discount CAP to a fixed credit percent of income CAP in October 2016, so the energy burdens in this study reflect the previously-structured CAP.

Table 3-5
NGDC CAP Energy Burden Levels for Heating Customers at 101-150% of FPIG 2012-2016



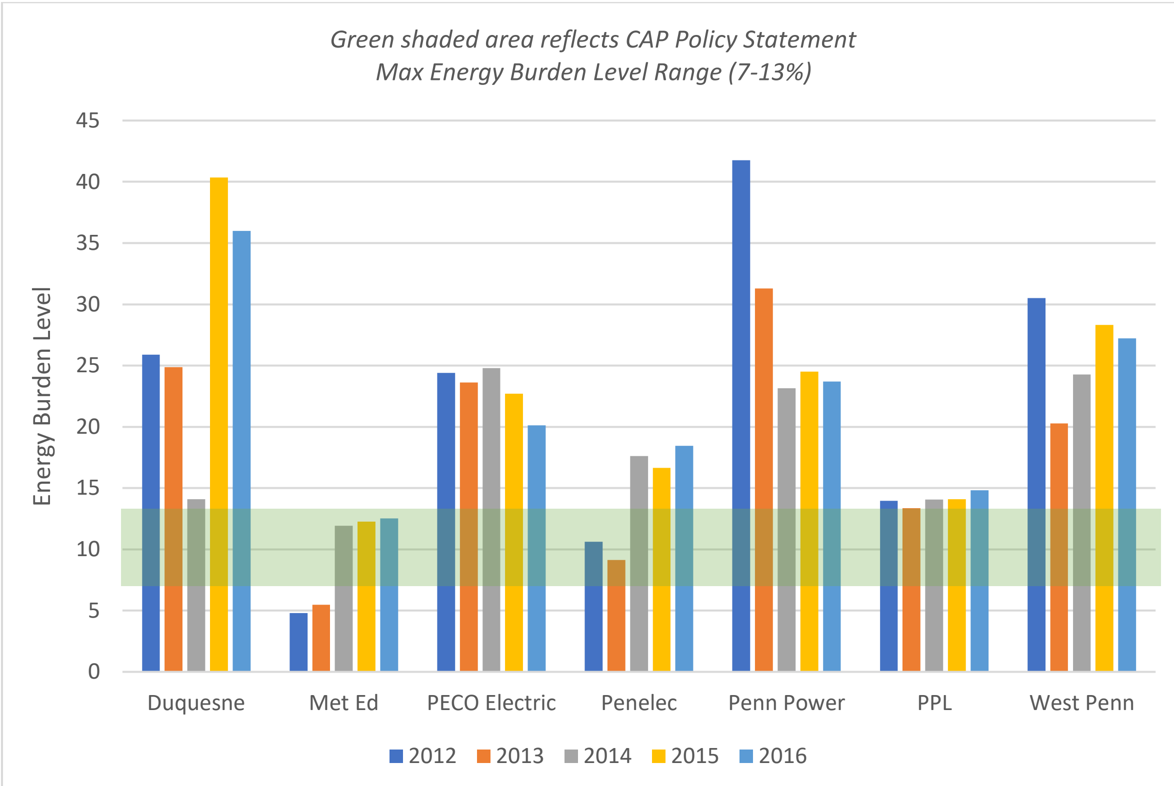
As seen in Table 3-5 above, most NGDC CAP customers with incomes between 101 and 150% of the FPIG had energy burdens at or below the CAP Policy Statement guidelines of 9 to 10%. CAP customers in Columbia, both Peoples utilities, and both UGI utilities had energy burdens of less than 9 to 10%. Columbia had a consistent average energy burden of 3%.[31] Peoples Gas' energy burdens ranged between 5-6%, Peoples Equitable between 5 and 9%, UGI Gas between 4 and 8%, and UGI Penn between 5 and 8%.

PGW CAP customers paid on average between 10% and 11% of income for CAP bills and thus had energy burdens during the five years of this study which were above the range in the CAP Policy Statement guidelines. In-program arrears may have also added to the monthly CAP bill of some PGW CAP customers and may account for why energy burdens were on average over 10%.

[31] Columbia Gas is the only NGDC whose CAP customers with incomes in the 51 to 100% and 101 to 150% FPIG groups were billed on average below the CAP Policy Statement guidelines.

EDC CAP Customers

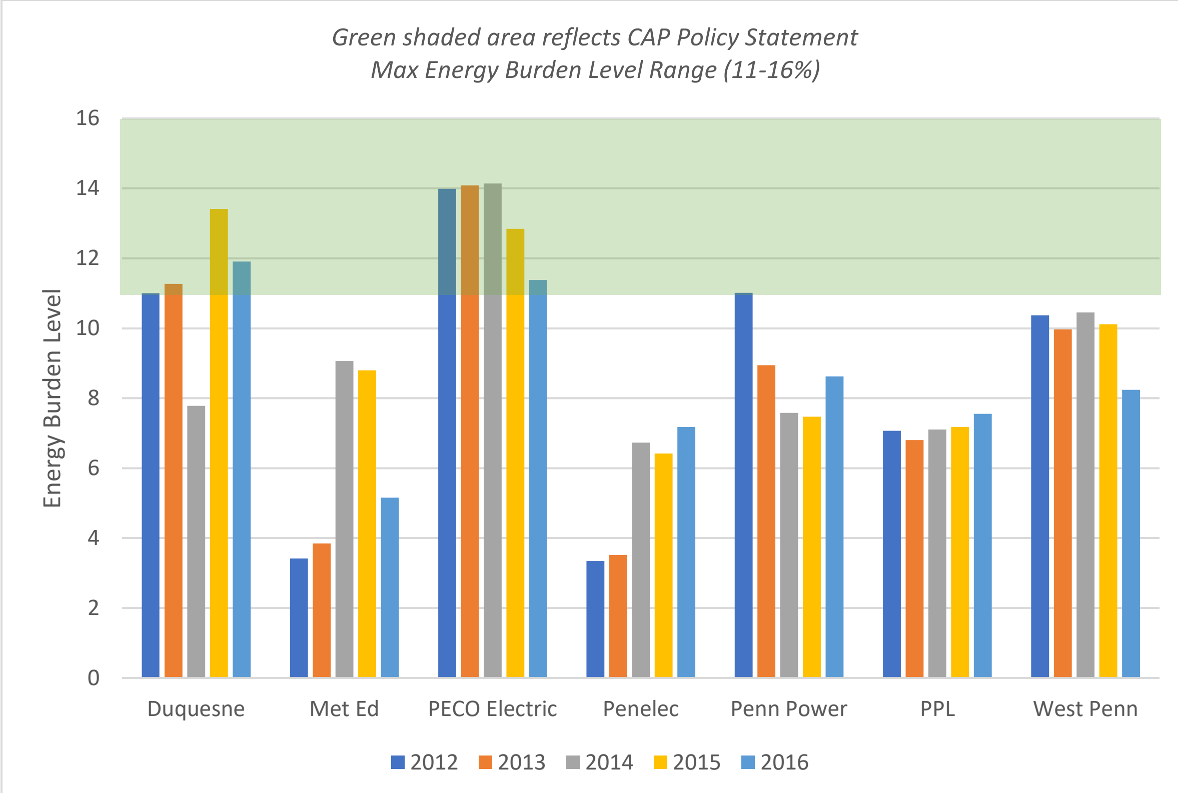
Table 3-6
EDC CAP Energy Burden Levels for Heating Customers at 0-50% of FPIG 2012-2016



As seen in Table 3-6, EDC CAP customers of Duquesne, Penelec, Penn Power, PPL, West Penn, and PECO Electric at the 0 to 50% FPIG level with electric heating accounts exceeded the CAP Policy Statement energy burden range of 7 to 13%. The average energy burdens for most EDC CAP customers at this income level exceeded this range. Met-Ed is the only EDC with energy burden levels within the CAP Policy Statement range for this income category.[32] Most EDC CAP heating customers within this income category had average energy burden levels exceeding 20% for most years in this study. However, it is unclear whether utilities included zero-income customers in the data used for these energy burden calculations.

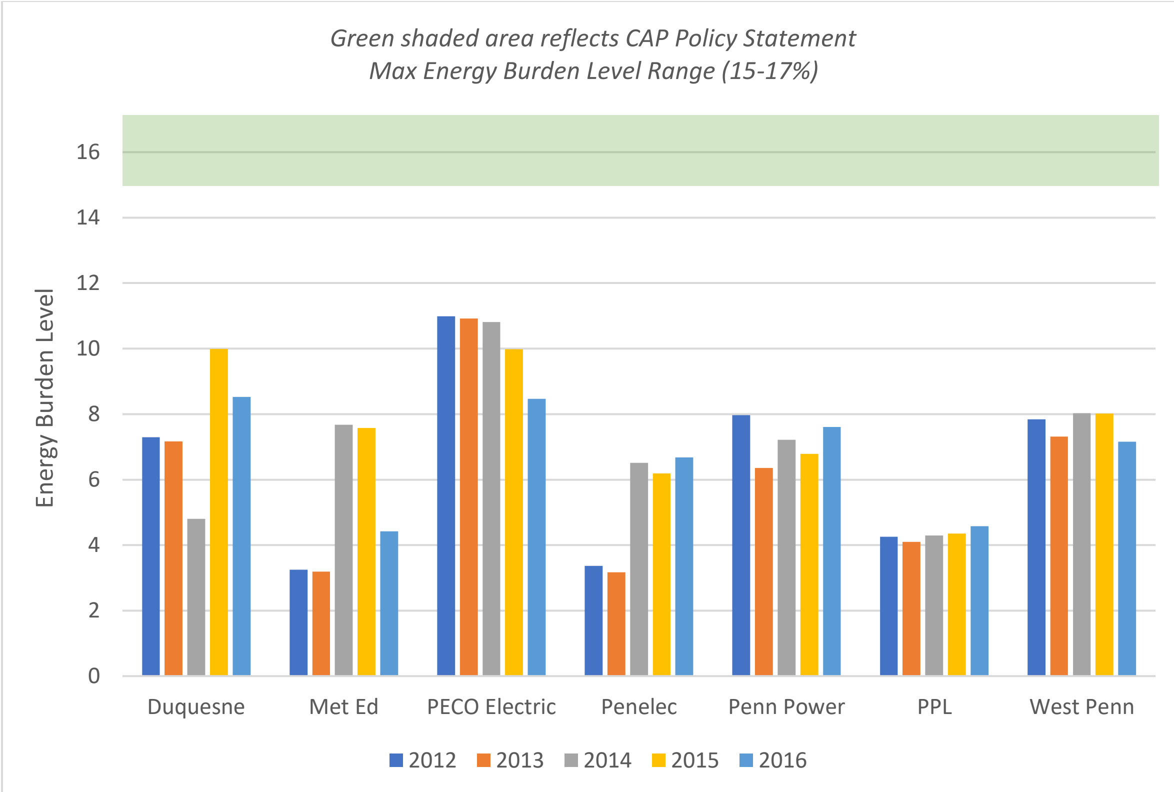
[32] The other FirstEnergy companies (*i.e.*, Penelec, Penn Power, and West Penn) have energy burden levels above the 7 to 13% CAP Policy Statement guidelines. It is not clear why Met-Ed's- energy burden levels are lower. In general, all FirstEnergy Companies calculate a CAP heating bill based on 9% of household income for this FPIG level.

Table 3-7
EDC CAP Energy Burden Levels for Heating Customers at 51-100% of FPIG 2012-2016



As seen in Table 3-7, all utilities were below or within the CAP Policy Statement maximum energy burden range of 11-16%. PECO Electric and Duquesne CAP heating energy burdens were within this range. The remainder of the EDCs had CAP energy burdens at or below 11%.

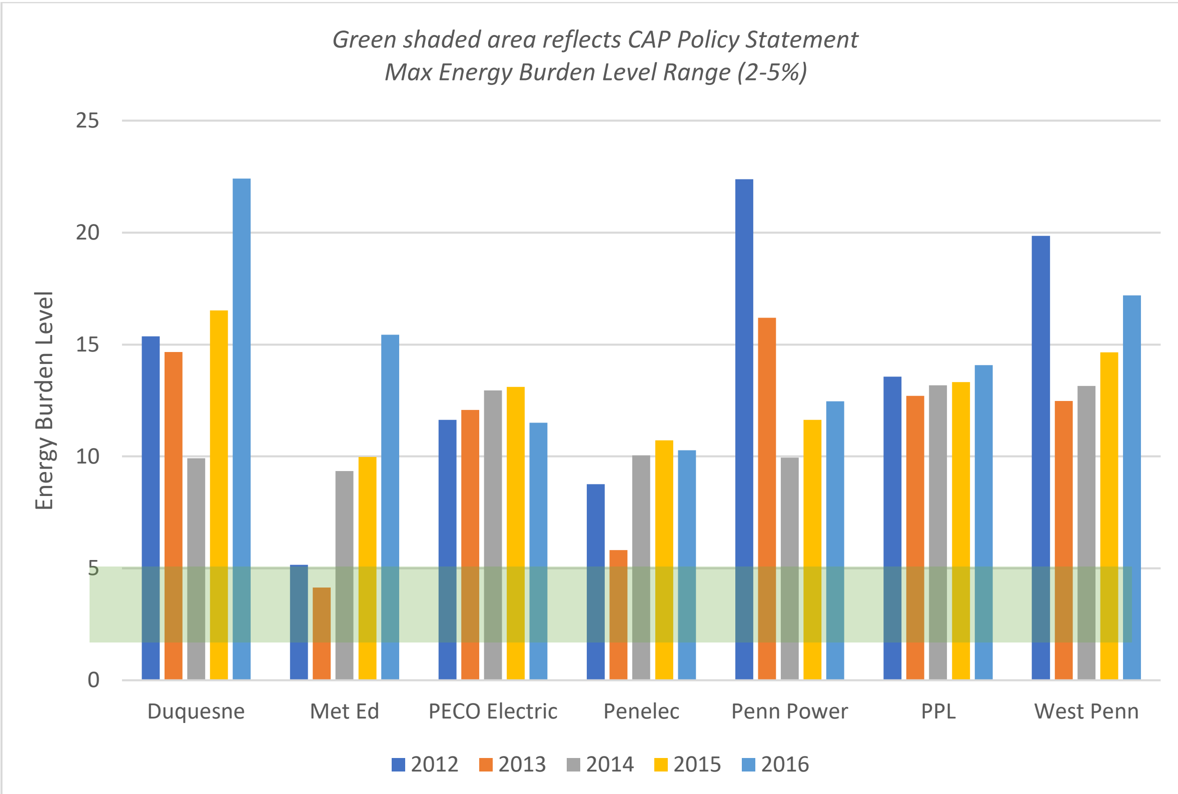
Table 3-8
EDC CAP Energy Burden Levels for Heating Customers at 101-150% of FPIG 2012-2016



The CAP Policy Statement suggests a maximum energy burden of 15-17% for electric heating customers in households in the 101 to 150% FPIG group. Section 69.265(2)(i)(C)(III). On average, EDC CAP heating customers with incomes between 101 to 150% of the FPIG had energy burdens well below the CAP Policy Statement maximum range of 15 to 17%. As seen in Table 3-8, most EDC CAP customers at this income level had energy burdens between 5 and 8% for most years in this study. PECO Electric's energy burden levels dropped from 11% to 9% from 2012 to 2016 for customers in this category.

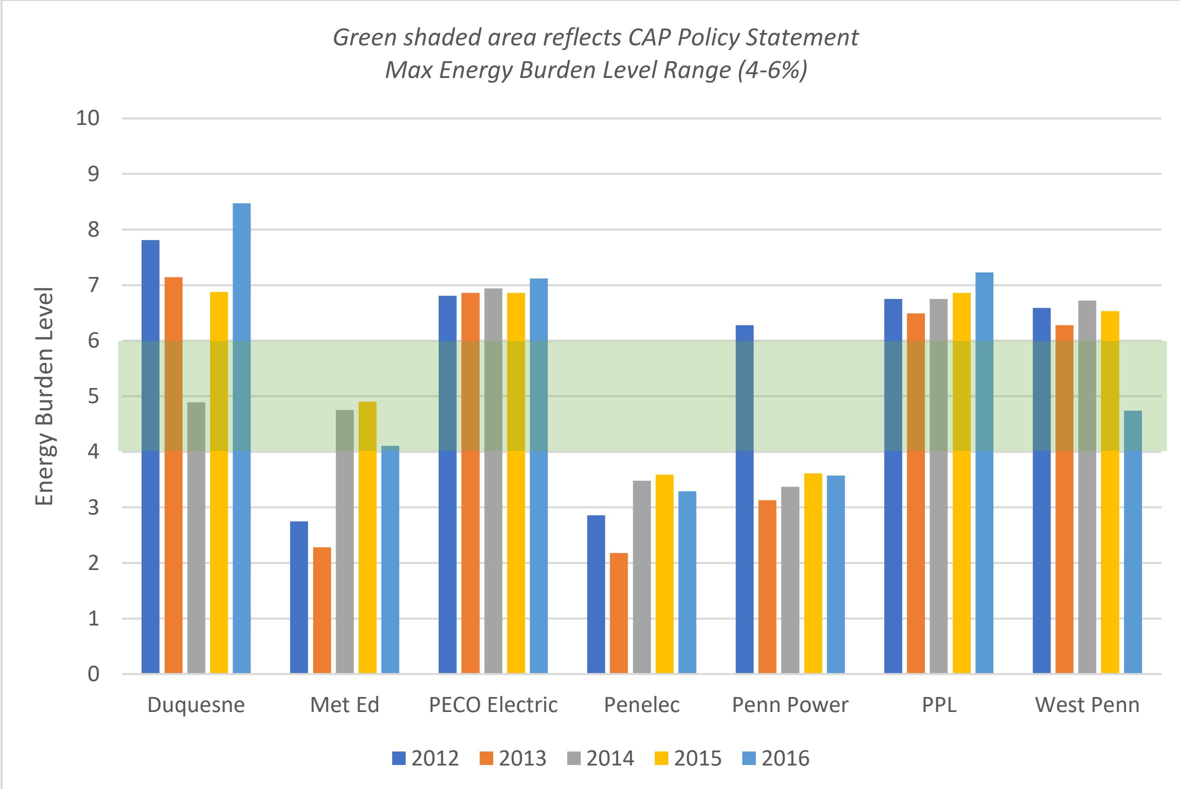
EDC CAP Non-Heating Customers

Table 3-9
EDC CAP Energy Burden Levels for Non-Heating Customers at 0-50% of FPIG 2012-2016



The CAP Policy Statement has a maximum energy burden range of 2-5% for EDC CAP non-heating customers with incomes at or below 50% of the FPIG. As seen in Table 3-9, all EDC CAP customers in this category exceeded this energy burden range, especially in the later years of the study. Most EDC non-heating CAP customers at this income level had energy burdens at or above 10% for most years in this study. However, as with the EDC CAP heating customers, it is unclear whether utilities included the zero-income customers in the data reported for this study.

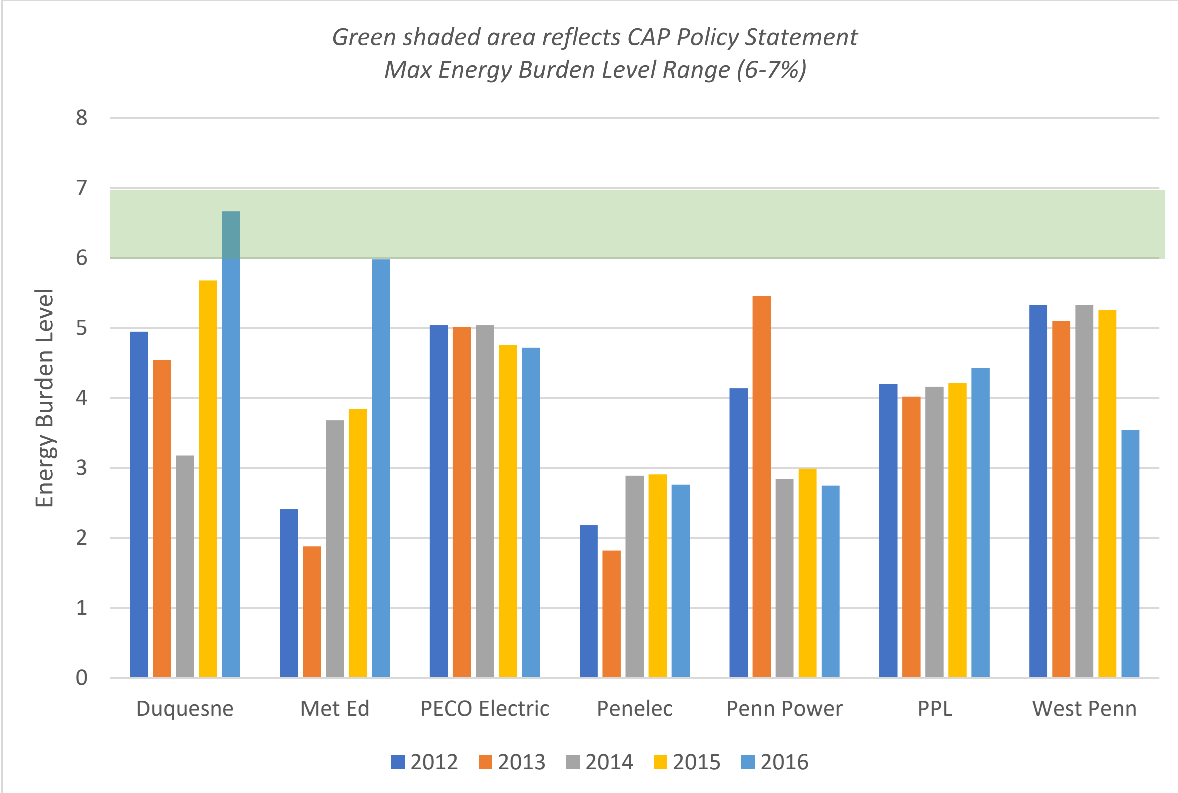
Table 3-10
EDC CAP Energy Burden Levels for Non-Heating Customers at 51-100% of FPIG 2012-2016



The CAP Policy Statement recommends a maximum energy burden range of 4 to 6% for EDC CAP non-heating customers with incomes between 51 and 100% of the FPIG. As seen in Table 3-10, over half of CAP customers in this category had energy burdens slightly above this range for most years of this study. Met-Ed, Penelec, and Penn Power non-heating CAP customers had energy burdens between 3% to 5%, and Duquesne CAP customers in this category increased from 5% to 8% from 2014 to 2016. However, this increase may have been due to Duquesne's budget billing issues that occurred during this time period. [33]

[33] Duquesne introduced a new billing system in November 2014 which did not retain prior usage data. Because its CAP bills were based on a percentage of budget billing, bills were considerably lower for most CAP customers through the beginning of 2015 but increased greatly thereafter, resulting in increased in-program arrears. Duquesne froze collections during this period so that CAP customers were not terminated for non-payment. *See Duquesne 2017-2019 USECP*, Docket No. M-2016-2534323, at 32-34 (order entered on March 23, 2017). CAP bills exceeded the maximum energy burdens in the CAP Policy Statement, and the Commission directed Duquesne to work with stakeholders to address CAP issues. March 23, 2017 Order at 28-31. By order entered on April 19, 2018, the Commission approved Duquesne's proposal to reduce the percent-of-bills discount (*i.e.*, rate discount) for most CAP customers in 2018 and switch to a percent-of-income (*i.e.*, PIPP) CAP by 2020.

Table 3-11
EDC CAP Energy Burden Levels for Non-Heating Customers at 101-150% of FPIG, 2012-2016



The CAP Policy Statement suggests a maximum energy burden range of 6% to7% for electric non-heating customers with income between 101% and 150% of the FPIG. As seen in Table 3-11, the energy burdens for most EDC CAP customers in this category fell below the CAP Policy Statement guidelines for all five years of this study. Duquesne CAP customers' energy burdens increased from 6% in 2015 to 7% in 2016. This increase was likely due to Duquesne's budget billing issues at this time.

Observations

From 2012 to 2016, the average energy burden was 7% to 8% for NGDC CAP heating customers, 5 to 6% for EDC non-heating CAP customers, and 8 to 10% for EDC CAP heating customers. Residential non-CAP customers had an average energy burden of 4% for gas and electric service during this time period.

Although not consistent across all income levels, the staff noted less variance in energy burdens of companies with percentage of income CAPs rather than rate discount CAPs.

On average, NGDC CAP customers at or below 50% of the FPIG level have energy burdens between 8% and 9% of their income, customers with incomes between 51% and 100% of FPIG have energy burdens between 7% and 8% of income, and customers with incomes between 101% and 150% of FPIG have energy burdens between 5% and 7% of their income. These ranges are within the CAP Policy Statement for all except customers at the 0 to 50% FPIG level.

There are numerous generalizations that can be made from the data provided by the EDCs. CAP customers in the lowest FPIG levels had the largest energy burden, and, as income increased, energy burdens tended to decrease across the board.

There has been variability in the energy burdens for CAP customers across Pennsylvania. As each utility determined its own CAP billing calculation, there was no discernable consistency across energy programs.

Customers in the 0 to 50% FPIG level, regardless of heating or non-heating status and energy type, often had energy burdens exceeding the CAP Policy Statement guidelines. Inclusion of zero-income customers by some utilities may have inflated the energy burden calculations for this FPIG level.

For the CAP customers in the 101 to 150% FPIG level, all three types of energy service show that both NGDC and EDC CAPs had energy burdens within the CAP Policy Statement guidelines. However, non-heating EDC CAP customer energy burdens at various FPIG levels seemed to exceed the CAP Policy Statement guidelines at a greater proportion than EDC heating CAP customers.

IV. Impact of LIHEAP Grants on Energy Burden Levels

Objective

As many states rely solely or primarily on LIHEAP funds as a means of energy assistance, this study examined the effect of LIHEAP grants on CAP customer bills to determine its impact on energy burden levels.

Background

LIHEAP is a federally-funded grant[34] that helps low-income households pay for their home energy[35] bills. Pennsylvania's LIHEAP is administered by DHS.[36] LIHEAP is traditionally available in Pennsylvania to eligible households from November through March, although DHS has extended the program into April when funding permits. Other states have summer cooling LIHEAP grants. LIHEAP grants are available to help pay for jurisdictional energy costs as well as deliverable energy costs. To qualify for Pennsylvania's LIHEAP, household income must be at or below 150% of FPIG, and the customer must be responsible for heating costs. 55 Pa. Code § 601.31 (1-2) (1988).[37]

LIHEAP offers two types of grants: Cash and Crisis. A LIHEAP Cash grant is available to all income-eligible customers that pay for their primary heating costs directly to a vendor or indirectly through rent. Section 601.31 (1-2) (1988). The amount of the LIHEAP Cash grant is calculated based on each household's gross income, number of occupants, county of residence, and source of heat (*i.e.*, electric, gas, oil, etc.). Section 601.41 (1988). From 2012 through most of 2016, the minimum amount of a LIHEAP Cash grant was $100, and the maximum amount was $1,000. For the 2016 - 2017 LIHEAP season (beginning November 2016), DHS increased the minimum Cash grant to $200. Households can receive only one LIHEAP Cash grant per LIHEAP season. Section 601.43 (1988).

A LIHEAP Crisis grant is available to all income-eligible households who are (1) responsible for paying for their primary or secondary heating costs directly or indirectly; and (2) are experiencing a home-heating emergency (*i.e.*, currently without heat or in imminent danger of being without heat). Section 601.32 (1-2) (1988). From 2012 through 2016, the minimum amount of a LIHEAP Crisis grant was $25, and the

---

[34] *See* 42 U.S.C. §§ 8621 – 8630. Low-Income Home Energy Assistance.
[35] "Home energy" means a source of heating or cooling in residential dwellings. 42 U.S.C. § 8622(6).
[36] Formerly the Department of Public Welfare.
[37] DHS changes aspects of the LIHEAP State Plan yearly, but the changes only affect some of the sections originally codified in Chapter 601 of Title 55 of the Pennsylvania Code. Citations to Title 55 of the Pennsylvania Code will only be to sections that have not changed over the time frame of the study. Citations to changed sections will be to the specific LIHEAP state plan for a given year.

maximum amount was $500.[38] Households could receive more than one Crisis grant, as long as the total amount of these grants did not exceed $500. Section 601.63 (1988).

In August/September of 2015 and 2016, DHS also administered a LIHEAP Summer Turn-On program that provided supplemental Crisis grants (up to $500) to households who had received LIHEAP Cash and/or Crisis grants during the previous season and are experiencing a heating emergency.[39]

Based on historical averages of the data reported by the utilities for 2013 to 2016, low-income CAP customers who assigned their LIHEAP grants to gas utilities received average Cash and/or Crisis grants of $361 for those in the 0 to 50% FGIP level, $258 for those in the 51 to 100% FPIG level, and $216 for those in the 101 to 150% FPIG level. Low-income CAP customers who assigned their LIHEAP grants to electric utilities received slightly more, on average. Cash and/or Crisis grants to electric heating utilities averaged $474 for the 0 to 50% FPIG level, $333 for the 51 to 100% FPIG level, and $282 for the 101 to 150% FPIG level. Non-heating CAP customers received an average of $417 in the 0 to 50% FPIG level, $319 in the 51 to 100% FPIG level, and $298 in the 101 to 150% FPIG level.

Most utilities apply LIHEAP Cash grants directly to the CAP customer's "asked to pay" amount" (ATP), in compliance with the Pennsylvania LIHEAP State Plan.[40] This means the grant is first applied to any in-program arrears, then the current bill. Any remaining amount is kept on the account as a credit toward the next month's bill.

Rather than rely on LIHEAP to address affordability concerns, Pennsylvania CAPs and other universal service programs are funded primarily and significantly through residential ratepayer rates.[41] DHS prohibits utilities from using LIHEAP grants to fund the discounts on a CAP bill or to reduce any debt forgiveness. DHS also prohibits pooling LIHEAP grants to fund CAPs or other universal service benefits.

[38] Households are ineligible for LIHEAP Crisis benefits if the grant does not resolve the home-heating emergency. "Emergency" is defined at 42 U.S.C. § 8622(1).

[39] If DHS determined a household was off or in termination status with both its primary and secondary heating sources (*i.e.*, gas and electric), a supplemental Crisis grant was issued to both utilities, up to $500 each (if the grant(s) resolved the termination or restored service). Thus, some customers received up to $1,000 in supplemental Crisis grants through the LIHEAP Summer Turn-On program.

[40] NFG is the only utility that applied LIHEAP Cash grants differently during this study period. NFG would apply a LIHEAP cash grant toward any past or current CAP charges. However, any remaining amount would be factored into a new budget billing calculation. The Commission ordered NFG to, among other things, comply with the LIHEAP State Plan and apply any remaining LIHEAP grant monies as a credit to the CAP customer's account. NFG 2017-2020 USECP at 10-18, 61-62, 65; Docket No. M-2016-2573847 (order entered on March 1, 2018).

[41] Other states use LIHEAP as the main source of funding for their energy assistance programs.

Methodology

Staff compared the average energy burdens of CAP customers before and after they received a LIHEAP grant to determine the impact that LIHEAP grants have in making CAP bills more affordable. Staff examined the following information for CAP customers who received LIHEAP: total number of customers who received LIHEAP, average usage, average billing, average income, and the total amount of LIHEAP dollars received. Most utilities provided this data by FPIG level and heating type.

The impact of the LIHEAP grants on CAP energy burden levels was determined by comparing the average energy burdens for CAP customers prior to receiving LIHEAP and then after the annual LIHEAP amount is applied to their average bill. This analysis examined the change in energy burdens for each FPIG level and heating type.

The CAP energy burdens in this analysis are not comparable to the average energy burdens for CAP customers identified in Section III, *Energy Burden Levels for Gas and Electric Service*. This inconsistency is primarily due to the count of LIHEAP households during a calendar year. The number of CAP customers who received LIHEAP includes each household that received a LIHEAP Cash and/or Crisis grant during a LIHEAP season. Since a calendar year encompasses two partial LIHEAP seasons (*i.e.*, January to March and November to December), households are counted twice if they received a grant in both seasons for the same calendar year. In 2015 and 2016, a CAP household could be counted three times if it received a grant in both seasons and also received a LIHEAP Summer Turn-On grant.

There could also be differences in the value of LIHEAP grants received during each calendar year by a given household. From 2012 through 2014, a CAP customer may have received multiple LIHEAP grants within a calendar year: two CASH grants (January to March and November to December) and Crisis grant(s) (up to $500 total/season). In 2015 and 2016, a CAP customer may have received an additional one or two Summer Turn-On grants.

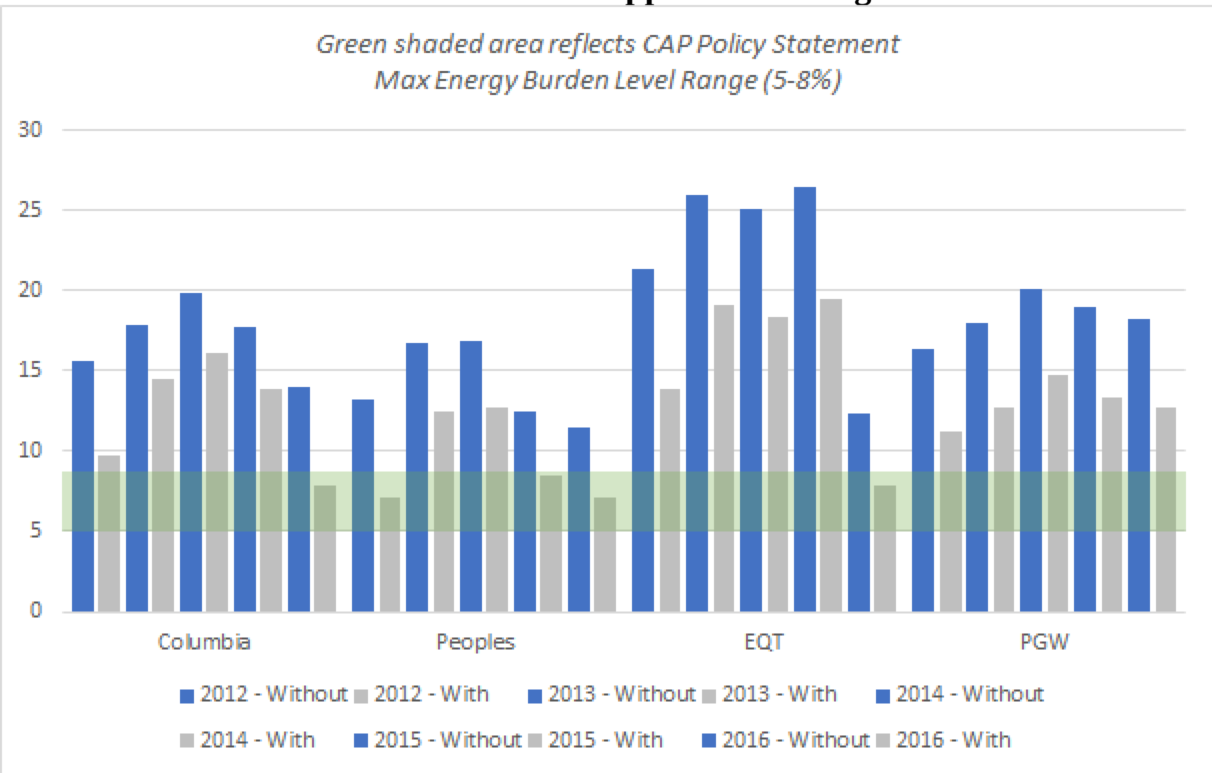
Data Limitations

UGI Gas, UGI PNG, and PECO Gas are not included in this part of the analysis because these utilities could not provide average annual income for CAP customers who received LIHEAP. NFG could not provide data by FPIG level, so it is included only in the analysis of CAP customers at the aggregate income level (*i.e.*, up to 150% of the FPIG).

Analysis

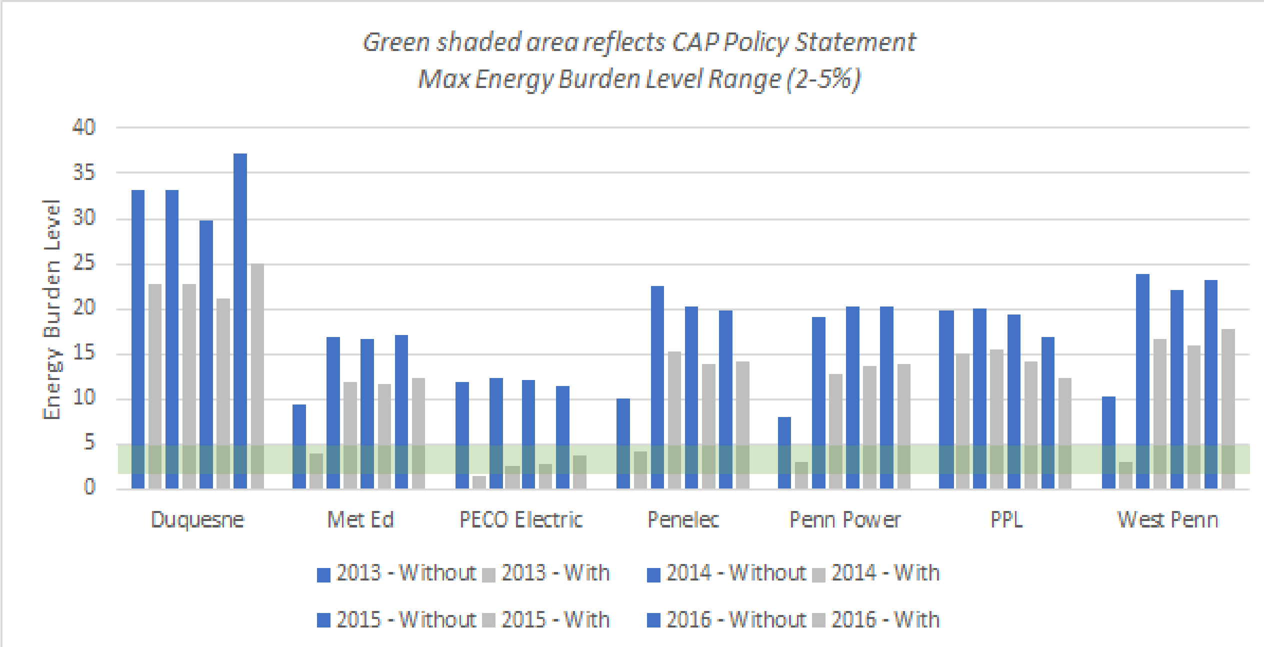
Average Impact of LIHEAP for CAP Customers at 0-50% of FPIG

Table 4-1
NGDC CAP LIHEAP Recipients at 0-50% FPIG
Without & With LIHEAP Grants Applied to Average Bills 2012-2016



The average impact of LIHEAP on energy burdens was greatest for CAP households with the lowest incomes. Based on the industry average, the energy burdens for NGDC CAP customers with incomes at or below 50% of the FPIG decreased by over 5.47 percentage points after receipt of LIHEAP, from 17.74% to 12.27%. For the customers of some individual NGDCs, LIHEAP grants provided a nearly 50% reduction in their energy burdens. Table 4-1 shows the pre- and post-LIHEAP energy burdens for NGDC CAP customers with incomes at 0-50% who received LIHEAP.

Table 4-2
EDC Non-Heating CAP LIHEAP Recipients at 0-50% FPIG
Without & With LIHEAP Grants Applied to Average Bills 2013-2016



EDC non-heating CAP customers at 0% to 50% FPIG experienced an industry average energy burden decrease of over 7.16 percentage points after LIHEAP grants were applied to the average annual bill, from 18.47% to 11.31%. Table 4-2 shows the pre- and post-LIHEAP energy burdens for EDC non-heating CAP customers with incomes at 0 to 50% who received LIHEAP. EDC CAP customers with electric heat at this FPIG level saw the biggest benefits from LIHEAP. Their industry average energy burdens decreased by over 7.68 percentage points after receipt of LIHEAP, from 27.07% to 19.39%.

Table 4-3
EDC Heating CAP LIHEAP Recipients at 0-50% FPIG
Without & With LIHEAP Grants Applied to Average Bills 2013-2016

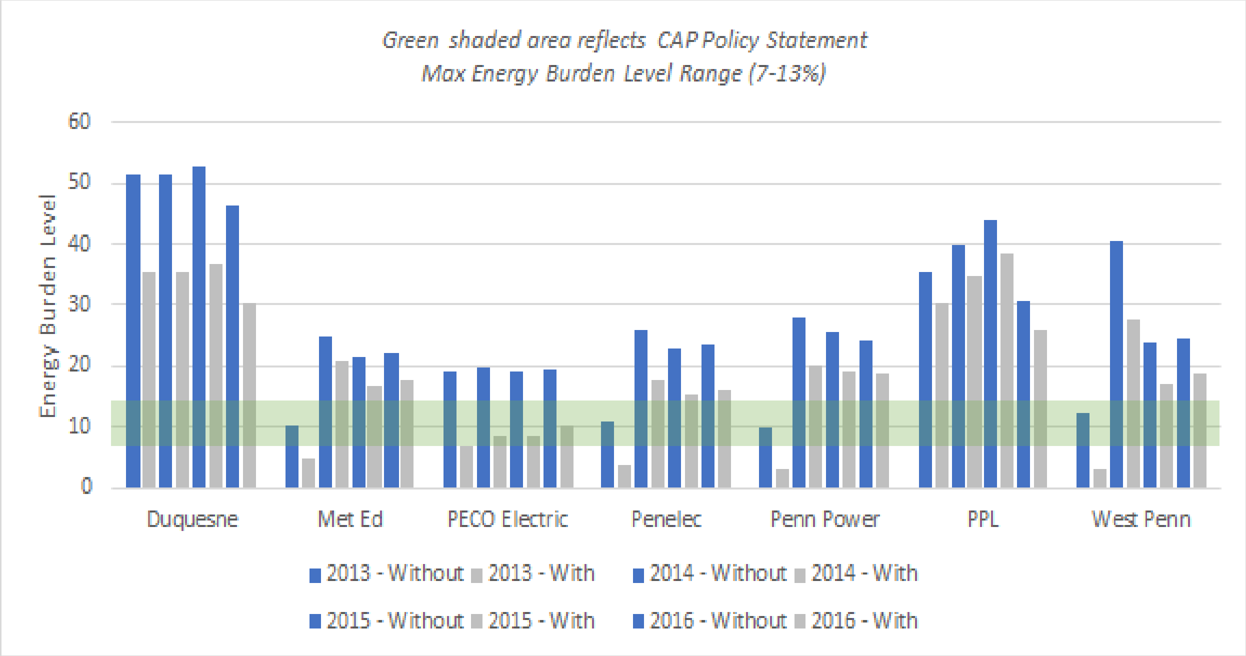


Table 4-3 shows the pre- and post-LIHEAP energy burdens for EDC CAP heating customers with incomes at 0 to 50% who received LIHEAP.

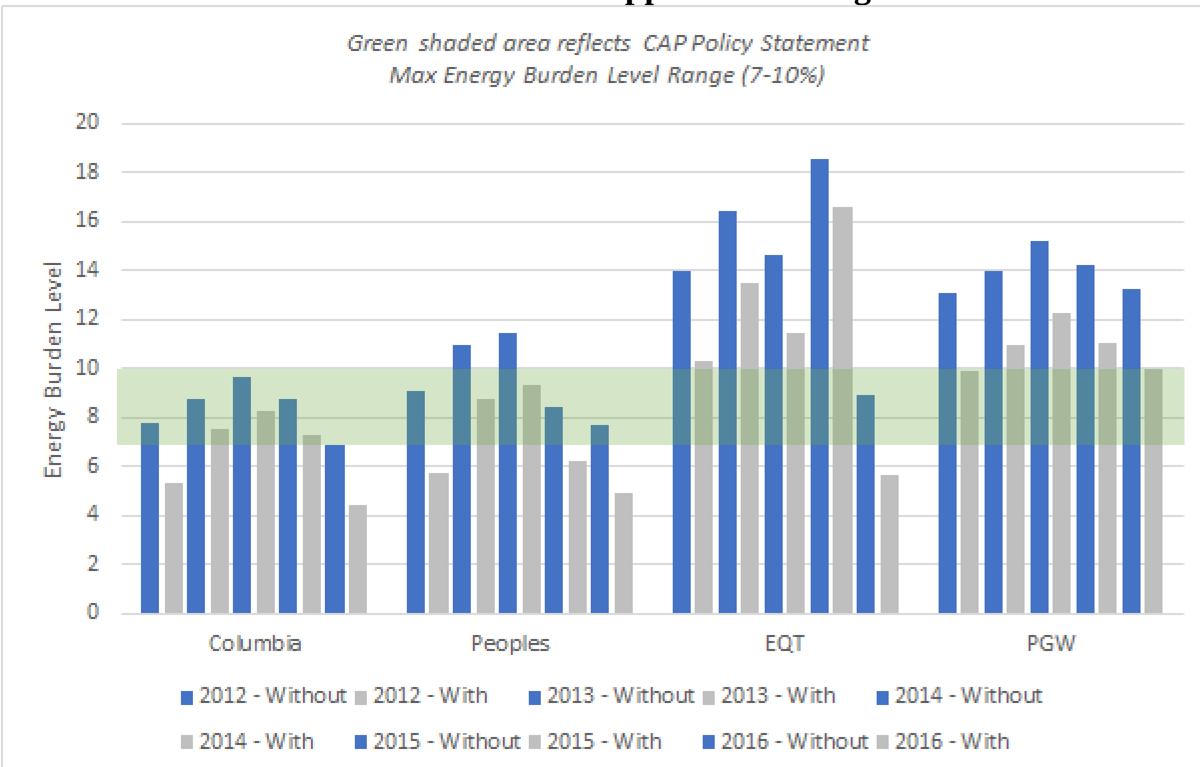
Average Impact of LIHEAP for CAP Customers at 51-100% of FPIG

Table 4-4
NGDC CAP LIHEAP Recipients at 51-100% FPIG
Without & With LIHEAP Grants Applied to Average Bills 2012-2016



As seen in Table 4-4, based on the industry average, LIHEAP reduced the energy burdens for NGDC CAP customers with incomes between 51 and 100% of the FPIG by over 2.69 percentage points, from 11.43% to 8.74%.

Table 4-5
EDC Non-Heating CAP LIHEAP Recipients at 51-100% FPIG
Without & With LIHEAP Grants Applied to Average Bills 2013-2016

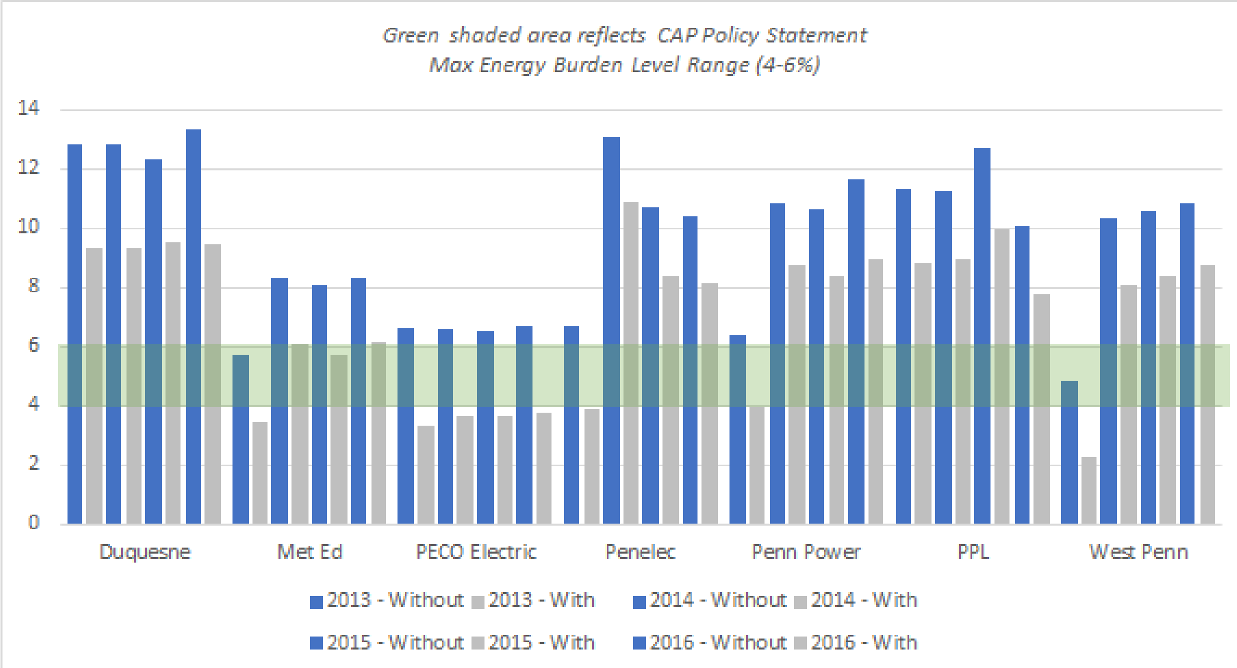


Table 4-6
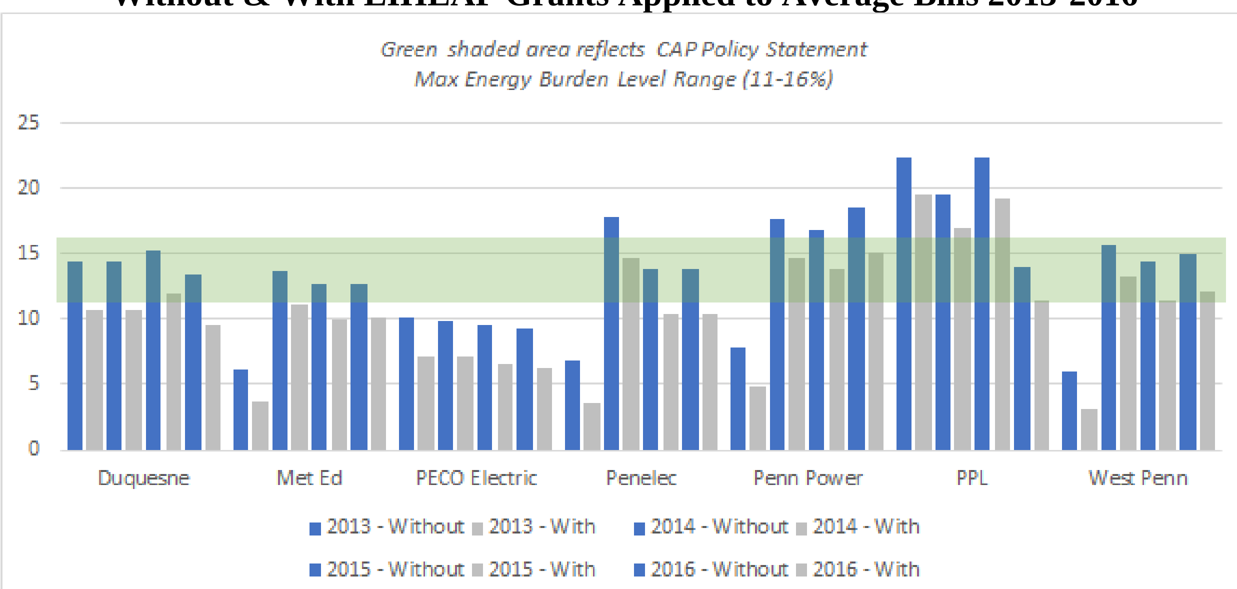
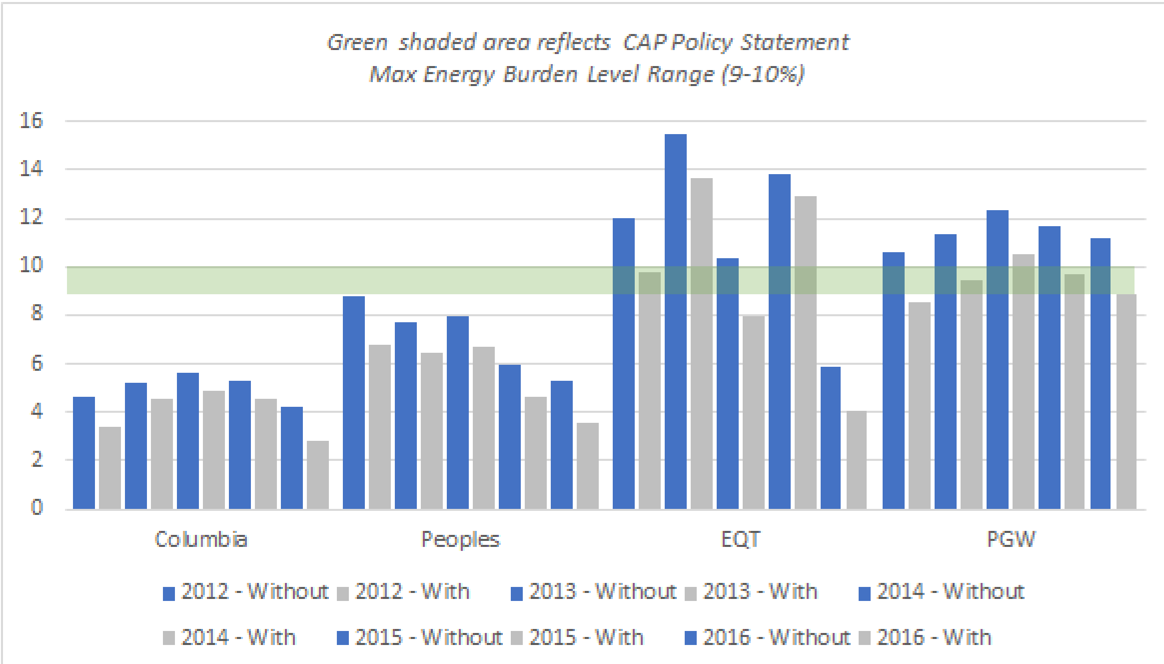
EDC Heating CAP LIHEAP Recipients at 51-100% FPIG
Without & With LIHEAP Grants Applied to Average Bills 2013-2016



EDC non-heating CAP customers with incomes between 51% and 100% of FPIG level experienced an industry average energy burden decrease of over 2.59 percentage points, from 9.81% to 7.22%, after applying LIHEAP to their average annual bills. The industry average energy burdens for EDC heating CAP customers at this FPIG level decreased by over 2.94 percentage points, from 14.39% to 11.45%, after applying LIHEAP to their average bills. Tables 4-5 and 4-6 show the pre- and post-LIHEAP energy burdens for EDC non-heating and heating CAP customers with incomes between 51 and 100% of FPIG who received LIHEAP.

Average Impact of LIHEAP for CAP Customers at 101 to 150% of FPIG

Table 4-7
NGDC CAP LIHEAP Recipients at 101-150% FPIG
Without & With LIHEAP Grants Applied to Average Bills 2012-2016



NGDC CAP customers with incomes between 101 and 150% of FPIG experienced an industry average decrease of over 1.54 percentage points, from 8.41% to 6.87%, in their energy burden levels after receipt of LIHEAP. Tables 4-7 shows the pre- and post-LIHEAP energy burdens for NGDC CAP customers with incomes at 101% to 150% FPIG level who received LIHEAP.

Table 4-8
EDC Non-Heating CAP LIHEAP Recipients at 101-150% FPIG
Without & With LIHEAP Grants Applied to Average Bills 2013-2016

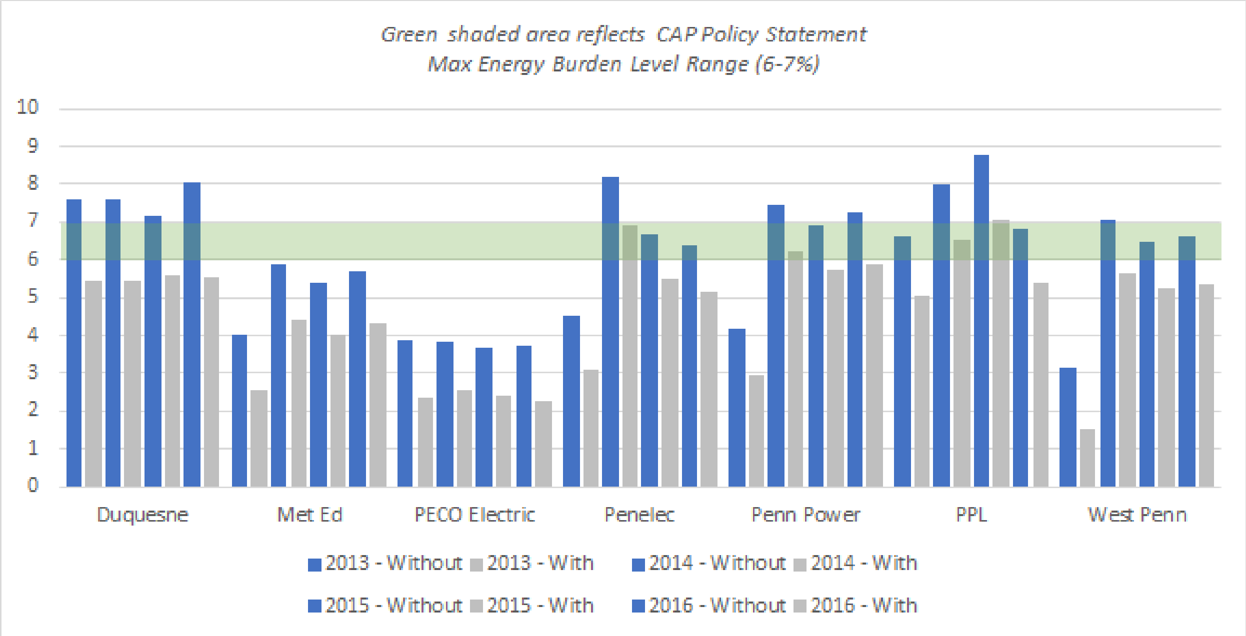


Table 4-9
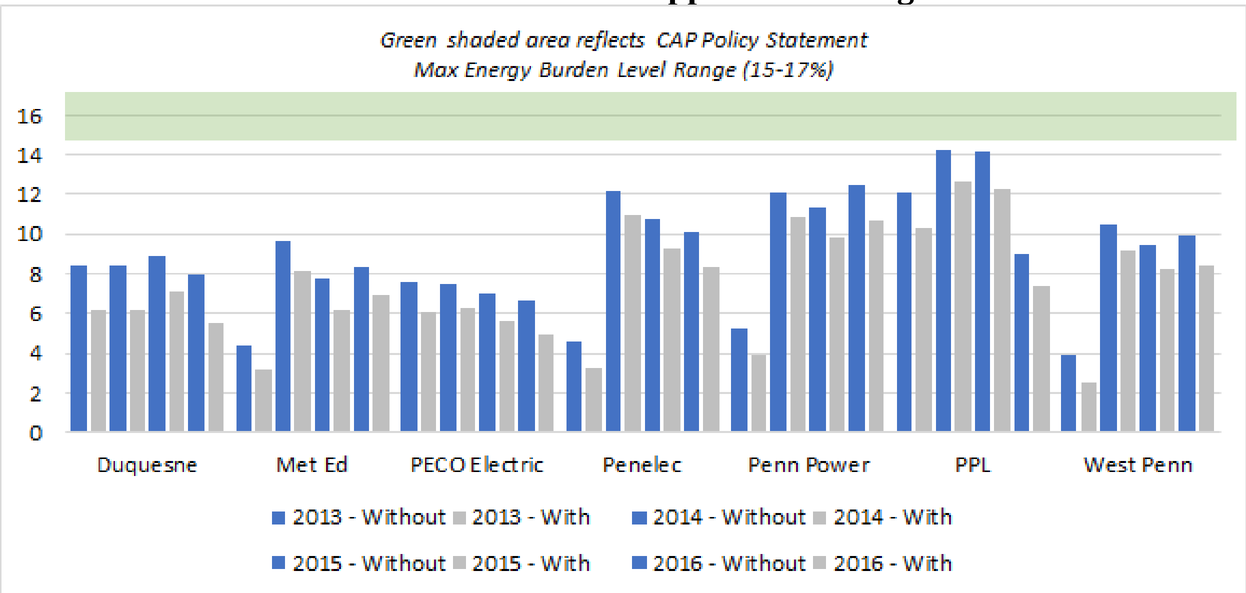
EDC Heating CAP LIHEAP Recipients at 101-150% FPIG
Without & With LIHEAP Dollars Applied to Average Bill 2013-16



EDC non-heating CAP customers at this FPIG level experienced an industry average energy burden decrease of over 1.5 percentage points, from 6.28% to 4.78%, after LIHEAP grants were applied to their average annual bills. The industry average energy burden for EDC heating CAP customers at this FPIG level decreased by over 1.57 percentage points, from 9.7% to 8.13%, after LIHEAP grants were applied to their average bills. Tables 4-8 and 4-9 show the pre- and post-LIHEAP energy burdens for EDC CAP customers with incomes at 101 to 150% of FPIG who received LIHEAP.

Observations

The analysis reflects that LIHEAP has a measurable impact on energy burdens for CAP customers.

After applying LIHEAP, CAP customers with incomes at or below 50% FPIG level experienced an energy burden decrease of approximately 5 to 6 percentage points for gas heating, 6 to 8 percentage points for electric non-heating, and approximately 7 to 9 percentage points for electric heating. Even with these decreases, however, the average energy burden for CAP households at this FPIG level who received LIHEAP generally exceeded the maximum energy burden guidelines in the CAP Policy Statement.

After applying LIHEAP, CAP customers with incomes between 51 and 100% of the FPIG experienced an energy burden decrease of approximately 2 to 3 percentage points for gas heating and 3 percentage points for electric non-heating and heating. The energy burdens for some NGDC and EDC non-heating CAP customers at this income level remained above the CAP Policy Statement guidelines after application of LIHEAP.

After applying LIHEAP, CAP customers with incomes between 101 and 150% of the FPIG experienced an energy burden decrease of approximately 1 to 2 percentage points for gas heating, electric non-heating, and electric heating. The energy burden levels for NGDC and EDC CAP customers at this FPIG were generally below the CAP Policy Statement guidelines after application of LIHEAP.

LIHEAP had the most impact on reducing energy burdens for NGDC CAP customers in 2016, across all FPIG levels. This may suggest that more CAP customers assigned their LIHEAP grants to their gas utility that year or the introduction of the Summer Turn-On grants increased the amount of LIHEAP monies applied to NGDC CAP accounts.

V. Pre-Program Arrearages (PPAs) and In-Program Arrears

Objective

Determine what the amounts of PPA and/or in-program arrears accrued by CAP customers indicate about the affordability of utility CAPs and customer payment behavior.

Background

Pre-Program Arrearages (PPAs)

When a low-income customer is initially enrolled in a CAP, any balance due which was accrued prior to enrollment (*i.e.*, PPA) is deferred and is not counted as part of the customer's CAP balance. This allows the CAP customer to begin the program with a "clean slate" (*i.e.*, a zero balance).

Table 5-1
Minimum Time frames for Full Forgiveness of PPA

Minimum Time Frame	Utilities
One-year (1/12th forgiveness for each payment)	PECO Electric, PECO Gas
18 months (1/18th forgiveness for each payment)	PPL
Two-years (1/24th forgiveness for each payment)	Duquesne, NFG[42]
Three-years (1/36th forgiveness for each payment)	Columbia, FirstEnergy (Met-Ed, Penelec, Penn Power, and West Penn), Peoples Natural Gas, Peoples Equitable, PGW, UGI Gas, UGI PNG

Table 5-1 reflects the PPA forgiveness time frames for utility CAPs during the 5-year period of this study. Each time a household pays its monthly CAP bill, the utility forgives a portion of the household's deferred PPA balance.[43] The amount of time required for a CAP household to receive full PPA forgiveness differs by utility. The

[42] NFG's PPA forgiveness component was limited to 36 months. NFG forgave 1/24th of PPAs for each month CAP customers pay their CAP monthly bill in-full and forgave any missed months once the in-program CAP balance was satisfied. After 36 months, any remaining PPA balance was added to the customer's account. NFG 2017-2020 USECP at 13, Docket No. M-2016-2573847 (filed on April 2, 2018). No other utility CAPs imposed a time restriction on a CAP customer's opportunity to earn PPA forgiveness.
[43] Some utilities imposed a monthly PPA co-payment. The co-payment goes to reduce the CAP customer's PPA in conjunction with the proportional forgiveness earned by full CAP payments. Thus, a utility with a monthly PPA co-payment is not actually providing full forgiveness of the CAP customer's PPA.

utilities set the minimum period required to earn the PPA forgiveness.[44] Only one utility limited the amount of time a CAP customer can take to achieve full PPA forgiveness.

Higher PPA balances may indicate the unaffordability of pre-CAP bills (*i.e.*, full-tariff bills). Such balances could also indicate poor payment behavior. Customers enrolling in CAPs with higher PPA balances have been found to have less success in payment assistance programs.[45]

In-Program Arrears

One of the benefits of a CAP is that it attempts to provides the customer with an affordable monthly payment while the customer is in CAP. Regardless of any PPA, all customers start with a "clean slate" when they are first enrolled into CAP. If participants continue to accumulate arrearages while in CAP (*i.e.*, in-program arrearages), it may indicate that the monthly CAP payment is not affordable and/or that the customer has poor or ineffective payment habits.

Accrual of in-program arrears may also indicate problems with the utility's collection procedures. Most utilities report initiating collection efforts up to and including service termination activity or removal from CAP after one or two missed CAP payments. If collection activity or program removal is delayed, in-program CAP arrears may continue to accumulate.

Methodology

To determine the average amount of PPA and in-program arrears carried by CAP customers, staff reviewed the following data from NGDCs and EDCs for the period from 2012 through 2016:

- The number of CAP accounts with PPAs and the total dollar amounts of the PPAs; [46] and
- The number of CAP accounts with in-program arrears and the total dollar amount of these arrears.

[44] The CAP Policy Statement recommends PPA forgiveness over 24 to 36 months, contingent upon regular monthly payments by the CAP participant. Section 69.265(6)(ix).

[45] *Pathways to Success in Low-Income Energy Assistance Payment Programs: The Differential Effects of Customer Characteristics and Program Design on Payment Rates* at 8-9. Megan Campbell, Opinion Dynamics (2013). http://www.opiniondynamics.com/wp-content/uploads/2013/08/Pathways-to-Success-in-Low-Income-Energy-Assistance-Payment-Programs1.pdf

[46] These PPA balances reflected the amount of PPAs carried by CAP customers during each year. It does not reflect the average PPA balance of CAP customers when they enrolled in the program with a PPA.

Data Limitations

Some utilities could not provide PPA and in-program arrearage amounts by FPIG level or heating type (*i.e.*, electric heating and electric non-heating). Specifically:

- The FirstEnergy Companies could not provide PPA data by FPIG level.
- The FirstEnergy companies could not provide data by heating type for electric.

Some utilities could not provide PPA and in-program arrears data for every year of this study. Specifically:

- Columbia Gas could not provide data for 2012.
- West Penn could not provide data prior to 2015.
- Duquesne could not provide data prior to 2015.

Further, the PPAs and in-program arrears were not tallied in terms of the age of the debt.

As a result, staff analyzed the PPA and in-program arrearage amounts in the aggregate across all FPIG levels (*i.e.*, 0-150%). Electric heat and electric non-heating CAP accounts are combined.

Analysis

NGDCs–PPAs

For gas heating CAPs, staff found a variance in the amount of PPAs carried by CAP customers. Most gas utilities reported average PPA balances between $400 and $800 for CAP customers with a PPA. Columbia Gas had the lowest average amount of PPAs, ranging from $99 to $133 per CAP customer for the four years of data provided (2013-2016). PGW reported the highest average amount of PPA, ranging from $1,260 to $1,342 per CAP customer for 2012 through 2016.

One possible reason for the variance in the average amounts of PPAs between Columbia Gas and PGW may be the differences in their CAP enrollment restrictions. Columbia Gas will enroll any low-income customer with a heating account into its CAP if the customer is “payment troubled,” which is defined as having received a termination notice or having broken a payment agreement within the past 12 months or having been identified through a utility referral or credit scoring. Columbia Gas 2015-2018 USECP at 17, Docket No. M-2014-2424462 (filed on August 12, 2015). During the time-period of this study, PGW enrolled low-income customers into its CAP only if the percentage-of-income payment (*i.e.*, 8-10%) was the most affordable option. PGW 2014-2016 USECP at 9, Docket No. M-2013-2366301 (filed on September 22, 2014). Thus, low-income customers could qualify for Columbia Gas' CAP after two missed payments, while PGW customers may have had to wait to qualify until CAP offered the most affordable payment.

Overall, PPA balances trended downward for most gas utilities. This decrease may be attributable to the lower cost of natural gas[47] and the warmer winters Pennsylvania experienced after the polar vortex in 2014-2015. Columbia (with the lowest average PPAs) and Peoples have, however, seen their average PPAs trend slightly upward over the five years.

Table 5-2
Average PPAs Carried by NGDC CAP Customers with PPA Balances (Gas Heating Only)

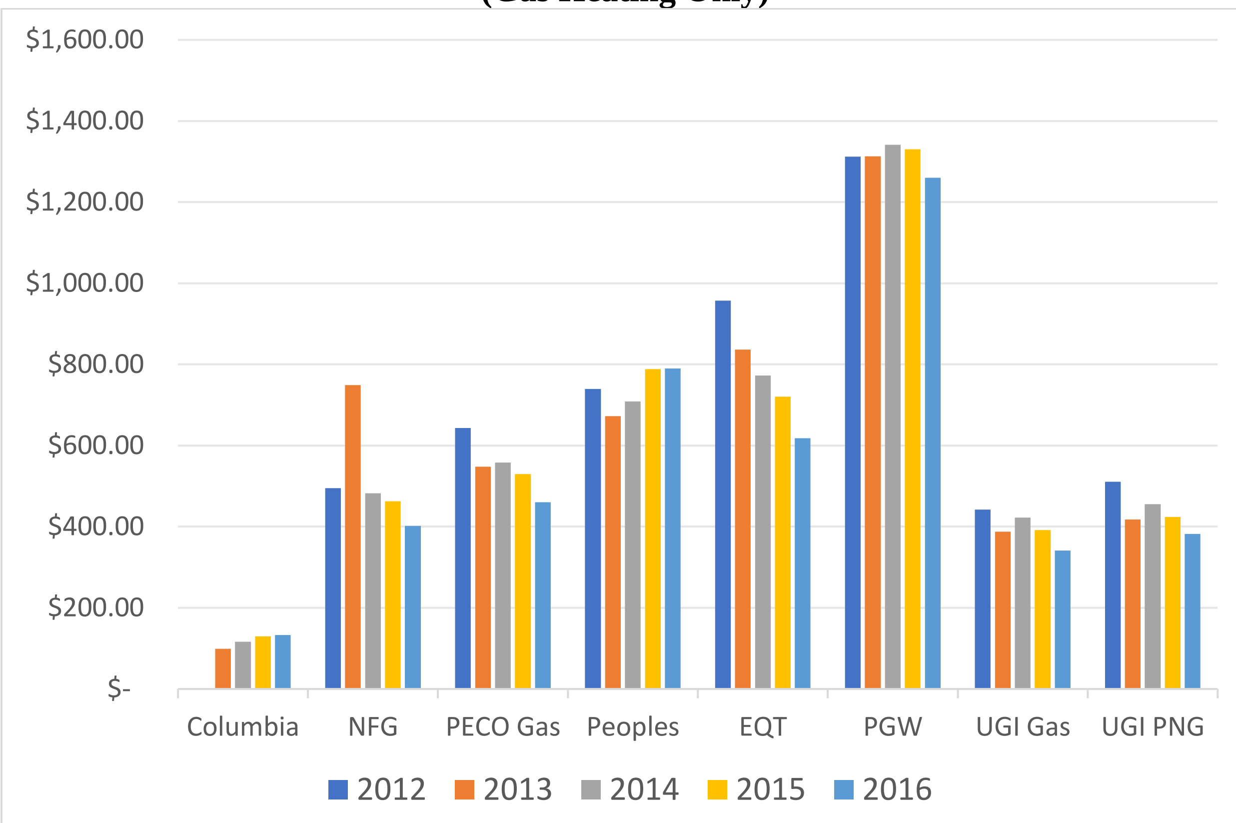


Table 5-2 reflects the average PPA per NGDC CAP customer with a PPA balance during the five-year- period of this study.

NGDCs–In-Program Arrears (IPAs)

Most NGDCs reported in-program arrears averaging from $100 to $400 for CAP customers who carried in-program arrears during 2012-2016. All NGDCs reported

[47] *See* the Commission's *Rate Comparison Reports*, published annually by the Commission's Bureau of Technical Services: http://www.puc.state.pa.us/filing_resources/rate_comparison_report.aspx

decreasing in-program arrearage balances in 2016. In addition to lower natural gas costs and warmer winters in 2015-2016, declining CAP enrollment may also be a factor. The average 2016 CAP enrollment rate for both NFG and Peoples Equitable declined by 43% compared to their average 2012 CAP enrollment rates. PGW's average CAP enrollment in 2016 was 34% lower than 2012. 2012 and 2016 Report on Universal Service Programs & Collections Performance at 39 and 59, respectively.

Table 5-3
Average IPAs Carried by NGDC CAP Customer with IPAs Balances
(Gas Heating Only)

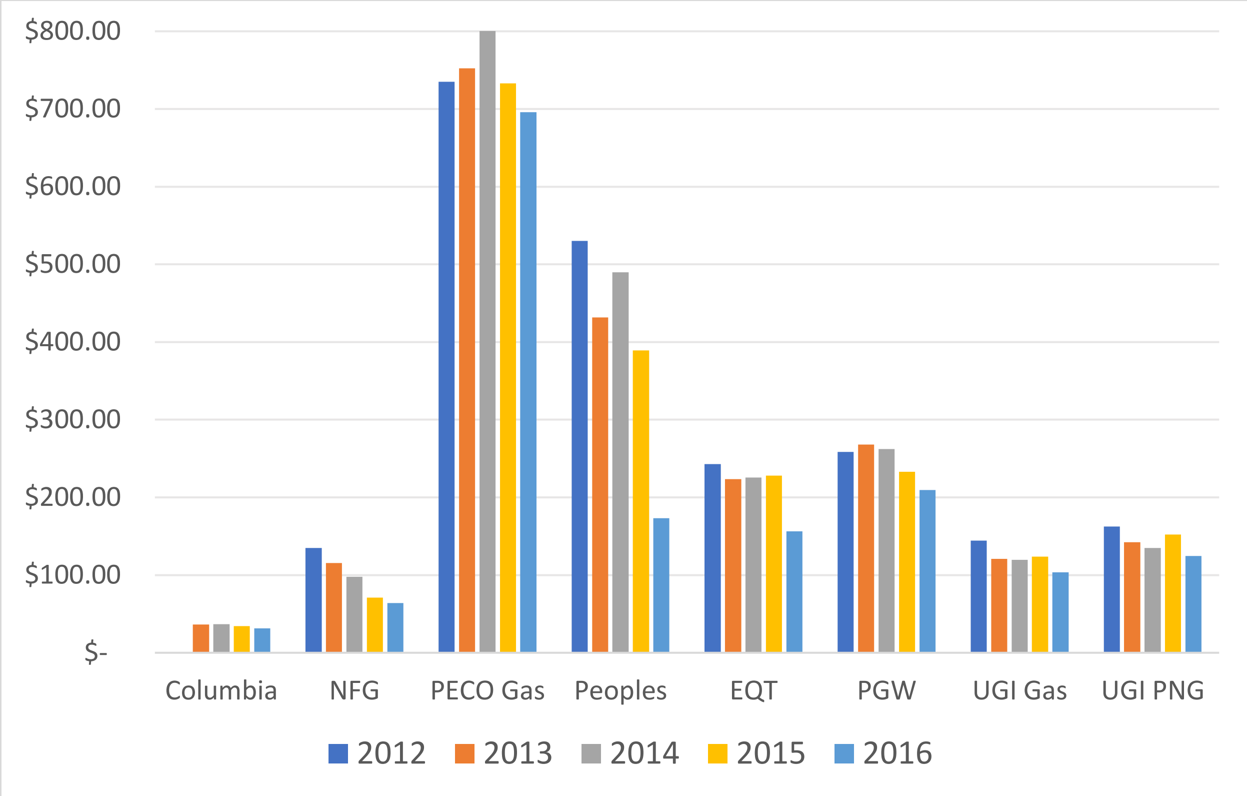

Table 5-3 reflects the average in-program arrears for NGDC CAP customers who carried in-program arrears during the five-year period of this study.

Columbia reported the lowest amount of in-program arrears, ranging from $31 to $36 for CAP customers who carried in-program arrears during the four years of data it provided (2013-2016). Columbia initiated termination procedures after two missed CAP payments,[48] and it also reported higher CAP termination rates, on average, than most other NGDCs. *See* Table 5-3. Beginning collection activity before a CAP customer accrues a sizeable in-program arrears may prevent CAP customers from accruing high in-program arrears balances, but, besides Columbia, this study did not detect a possible correlation between these two variables.

[48] Columbia 2015-2018 USECP at 21, Docket No. M-2014-2424462 (filed on August 12, 2015).

PECO Gas reported the highest amount of in-program arrears, ranging from $643 to $746 for CAP customers who carried in-program arrears for 2012 through 2016. During this period, PECO Gas had allowed CAP customers to obtain payment agreements[49] for in-program arrears which likely is responsible for its higher levels.[50]

EDCs – PPAs

Table 5-4
Average PPAs Carried by EDC CAP Customers with PPA Balances
(Electric Non-Heating and Electric Heating)

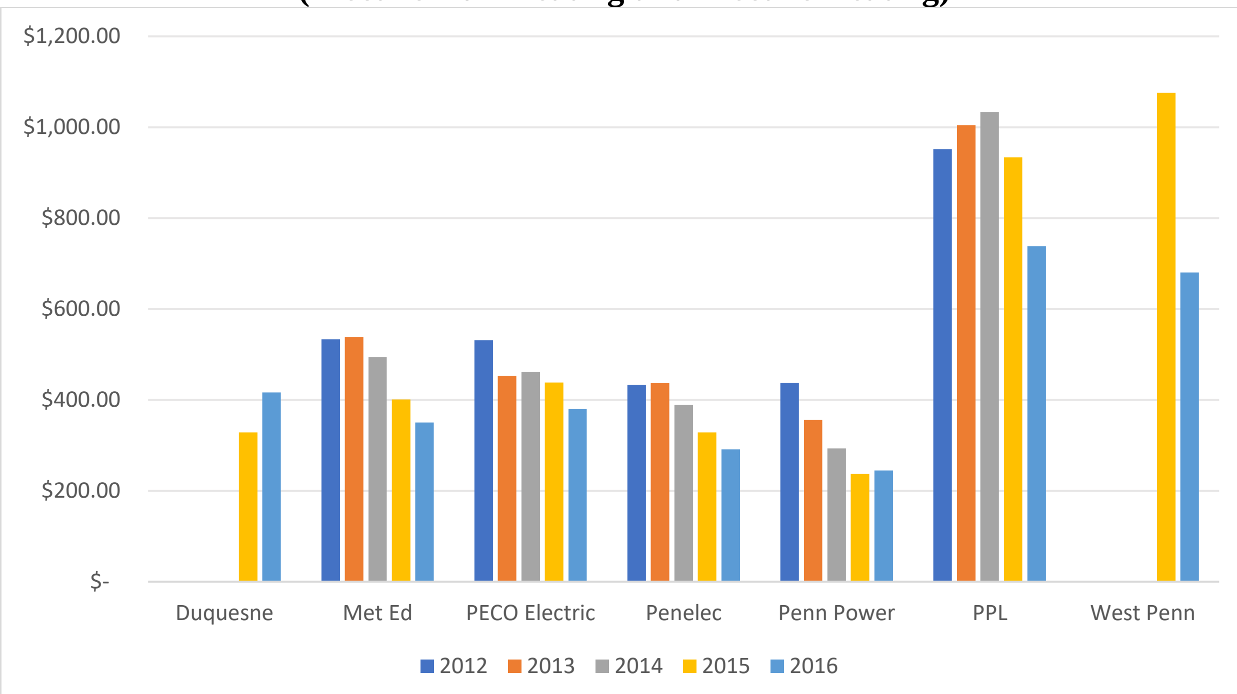

Table 5-4 reflects the average PPA amounts for EDC CAP customers who carried a PPA balance. Most EDCs reported a decrease in the average PPA balances carried by

---

[49] The Commission generally uses “arrangements” to refer to Commission-facilitated payment arrangements pursuant to Chapter 14 and “agreements” to refer to accords reached between the customer and the utility without Commission input. In this report, staff shall refer to both as “agreements.”

[50] PECO Gas and Electric allowed CAP customers to obtain payment agreements on in-program arrears as one way to address unaffordability, especially for customers with incomes below 50% of the FPIG. The availability of payment agreements, however, allowed CAP customers to accrue large amounts of in-program arrears. PECO reported that the combined gas and electric in-program arrears balance was approximately $45 million by July 2015. PECO 2016 - 2018 USECP at 36, Docket No. M-2015-2507139 (filed on February 17, 2017). The Commission approved PECO’s 2016 - 2018 USECP by order entered on August 11, 2018, which permitted PECO to alter its CAP structure to improve affordability for its lowest income customers. PECO also eliminated payment agreements for in-program arrears after October 2016. PECO 2016 - 2018 USECP at 9-10.

CAP customers by 2016. PPL and West Penn CAP customers, however, carried the highest amount of average PPAs for EDC customers with PPAs, peaking at $1,034 for PPL in 2014 and $1,076 for West Penn in 2015.[51, 52]

EDCs – In-Program Arrears

Table 5-5
Average IPAs Carried by EDC CAP Customers with IPA Balances
(Electric Non-Heating and Electric Heating)

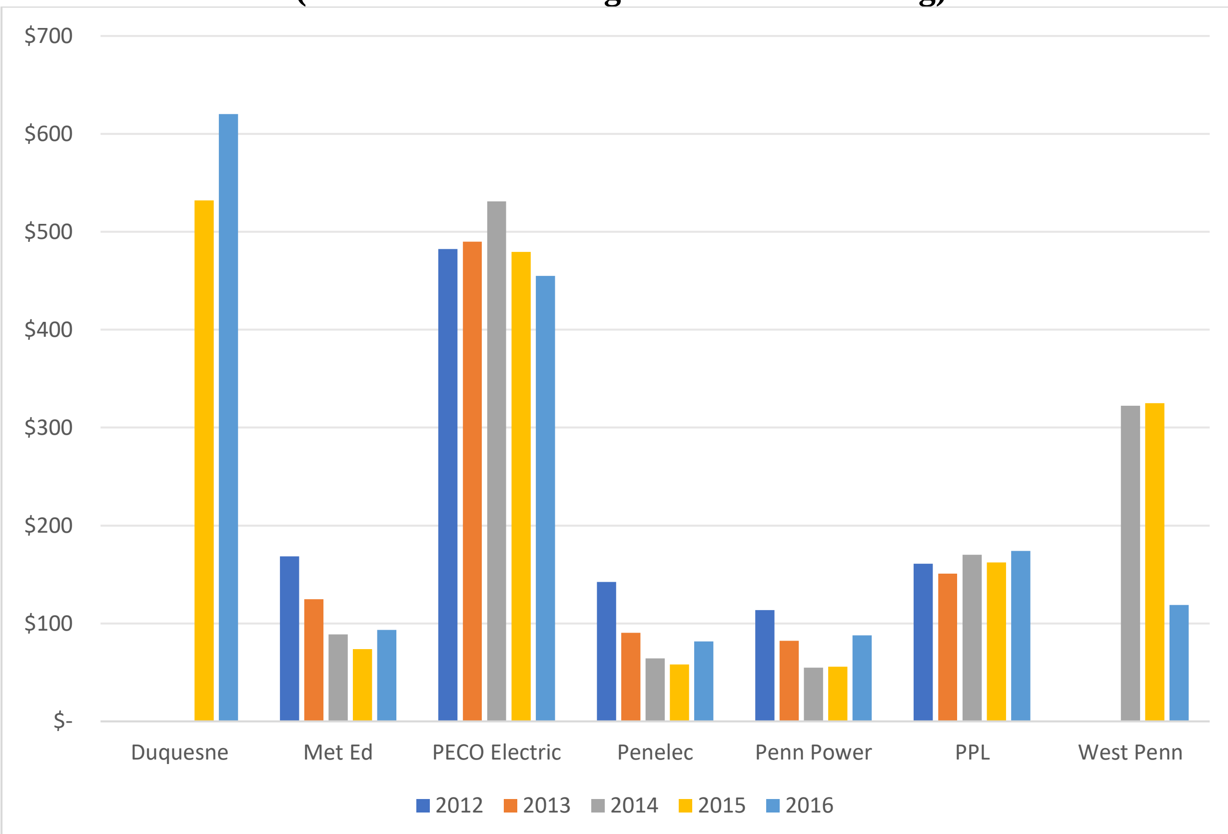

Table 5-5 reflects the average in-program arrears for EDC CAP customers who carried arrears during the five-year period of this study.

[51] PPL's high average PPA balances were likely a result of its CAP eligibility requirements during this time period. From 2011 through September 11, 2014, income-eligible customers must have defaulted on one or more payment agreements to qualify for PPL's CAP. PPL 2011-2013 USECP at 9, Docket No. M-2010-2179796 (filed on February 18, 2011). PPL subsequently amended this requirement by allowing any income-eligible customer who had a payment arrangement within the past 12 months to qualify for CAP. During the time frame of the study, PPL also required that customers have a PPA to enroll in CAP. PPL 2017-2019 USECP at 16-17 (filed on September 11, 2014), Docket No. M-2013-2367021, (order entered on November 6, 2017) at 16-17.

[52] In December 2015, West Penn converted all in-program arrears carried by CAP customers to PPA status. This may explain the high amount of PPAs reported by West Penn in 2015 and 2016.

Most EDCs reported an average in-program arrears balance of less than $200 per customer with an in-program arrears balance. Duquesne and PECO Electric reported the highest average in-program arrears carried by electric CAP customers.

Duquesne's average in-program arrears were $532 in 2015 and increased to $620 in 2016. Duquesne's higher in-program arrearage amounts are most likely result of the budget billing issues Duquesne experienced during this time. [53]

PECO Electric's in-CAP payment agreements, which paralleled its NGDC CAP payment agreements, likely contributed to the higher in-program arrears reported during this time period. [54]

Observations

With the collection and assessment of the data noted above, staff offers several observations:

- CAP eligibility requirements may have impacted the amount of PPA carried by customers when they enroll in the program. Utilities that restricted CAP enrollments to customers with a broken payment agreement to households which would pay less on a percent of income plan or to accounts with existing arrearages reported higher average PPA balances.

---

[53] Duquesne introduced a new billing system in November 2014 which did not retain prior usage data. Because its CAP bills were based on a percentage of budget billing, bills were considerably lower for most CAP customers through the beginning of 2015 but increased greatly thereafter, resulting in increased in-program arrears. Duquesne froze collections during this period so that CAP customers were not terminated for non-payment. See Duquesne 2017-2019 USECP, Docket No. M 2016 2534323, at 32-34 (order entered on March 23, 2017). CAP bills exceeded the maximum energy burdens in the CAP Policy Statement, and the Commission directed Duquesne to work with stakeholders to address CAP issues. March 23, 2017 Order at 28-31. By order entered on April 19, 2018, the Commission approved Duquesne's proposal to reduce the percent-of-bills discount (i.e., rate discount) for most CAP customers in 2018 and switch to a percent-of-income (i.e., PIPP) CAP by 2020.

[54] PECO Gas and Electric allowed CAP customers to obtain payment agreements on in-program arrears as one way to address unaffordability, especially for customers with incomes below 50% of the FPIG. The availability of payment agreements, however, allowed CAP customers to accrue large amounts of in-program arrears. PECO reported that the combined gas and electric in-program arrears balance was approximately $45 million by July 2015. PECO 2016 - 2018 USECP at 36, Docket No. M-2015-2507139 (filed on February 17, 2017). The Commission approved PECO's 2016 - 2018 USECP by order entered on August 11, 2018, which permitted PECO to alter its CAP structure to improve affordability for its lowest income customers. PECO also eliminated payment agreements for in-program arrears after October 2016. PECO 2016 2018 USECP at 9-10.

- PPA balances trended downward for most gas utilities. This decrease may be attributable to the lower cost of natural gas and the warmer winters Pennsylvania experienced after the polar vortex in 2014-2015.

- The data show in-program arrears were generally decreasing for all NGDCs from 2012 to 2016. Factors that may have contributed to this trend include lower natural gas costs, warmer winters, and declining CAP enrollments during this study period.

- Most EDC CAP customers with in-program arrears carried a balance of less than $200 during this five-year period.

- Since many utilities were unable to provide data for the PPA and in-program arrears balances by FPIG levels and/or by heating type, staff is unable to determine if customers at specific incomes (*e.g.*, at or below 50% of the FPIG) or with specific heating types carried a disproportionate share of CAP PPA or in-program arrears.

VI. Percentage of CAP Bills Paid In-Full

Objective

Explore whether the percentage of CAP bills paid in-full could be an indicator of energy affordability for CAP customers.

Background

CAPs are designed as alternatives to traditional collection methods for low-income, payment-troubled customers. In exchange for continued utility services, customers participating in CAPs agree to make regular monthly payments, which may be set at an amount less than the customer's current bill based on usage at tariff rates. While participation in a CAP does not guarantee that low-income, payment-troubled customers will receive the most economical bill for utility services, CAPs and other universal service programs are intended and designed to make those energy bills more affordable. Notwithstanding other factors that may affect a household's ability to pay its monthly home energy bills, it is presumed that CAP customers are more likely to pay their monthly home energy bills if those bills do not consume an unmanageable percentage of income for low-income, payment-troubled customers.

As discussed previously in this report, NGDCs and EDCs have discretion in many aspects of the design and operation of their CAPs, including determining the monthly payment amounts of each CAP participant. Section 69.265(2)(i)-(vi) of the CAP Policy Statement provides guidelines for determining how CAP monthly payment plans should be established, including providing maximum home energy burden guidelines for total electric and natural gas home energy costs. A majority of Pennsylvania utilities set CAP payment amounts based on the customer's household family size and gross monthly income or the customer's average monthly bill, whichever is less. *See* Table 3-1 for an overview of how the major utilities determine monthly CAP payment amounts, including the minimum monthly CAP payments established for those customers with no income.

Methodology

To assess whether monthly CAP bills are set at an amount that facilitates low-income customers to pay their monthly electric and/or natural gas bills in-full, the Commission requested CAP billing data from the major EDCs and NGDCs for the years 2012-2016. The data requested included the number of monthly CAP bills issued and the amount (in dollars) of those bills. The data submitted by the utilities were categorized by FPIG level and by account status (electric heating, electric non-heating, gas heating).

Data Limitations

Certain utilities experienced limitations regarding the availability of the data requested. For example, NFG could not provide the data requested for CAP customers by FPIG level; thus, Commission staff was not able to evaluate if there were differences in the percentage of bills paid among the FPIG levels within NFG's CAP. In addition, West Penn was unable to provide data for the years 2012 and 2013, and PPL could only provide estimated data for the years 2012-2015. Furthermore, the EDCs and NGDCs had no meaningful way to distinguish if "payment in full" data exclusively included a full payment on current monthly charges or if "payment in full" data included the full payment of current plus any delinquent or "catch up" amounts. Three of the FirstEnergy Companies, Met-Ed, Penelec, and Penn Power, submitted 2012 to 2015 data that showed several months of billings that were reported as negative dollar amounts. Therefore, although the Commission requested data regarding the dollar amounts of CAP billings and payments, staff was unable to use it in the analyses.

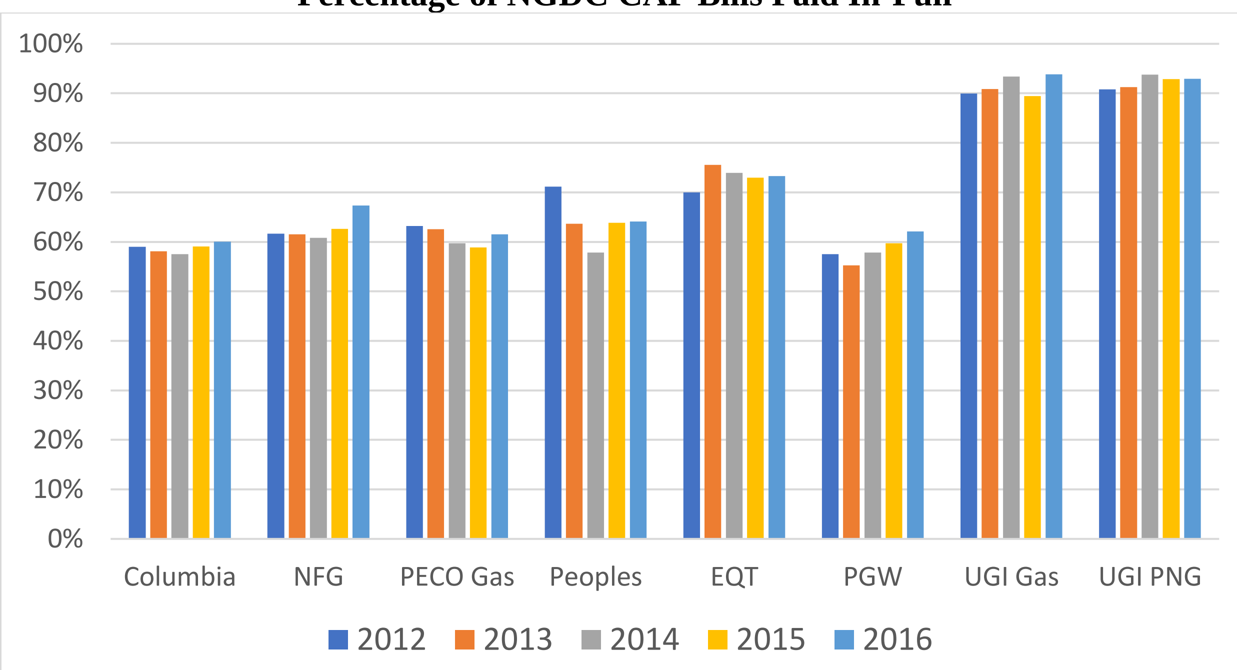
Analysis

CAP Customer Billing Data by Heating Type

This analysis is in two parts. Staff first examined the bill-paying patterns based on heating type. The second part looks at bill-paying patterns based on the customers' income levels.

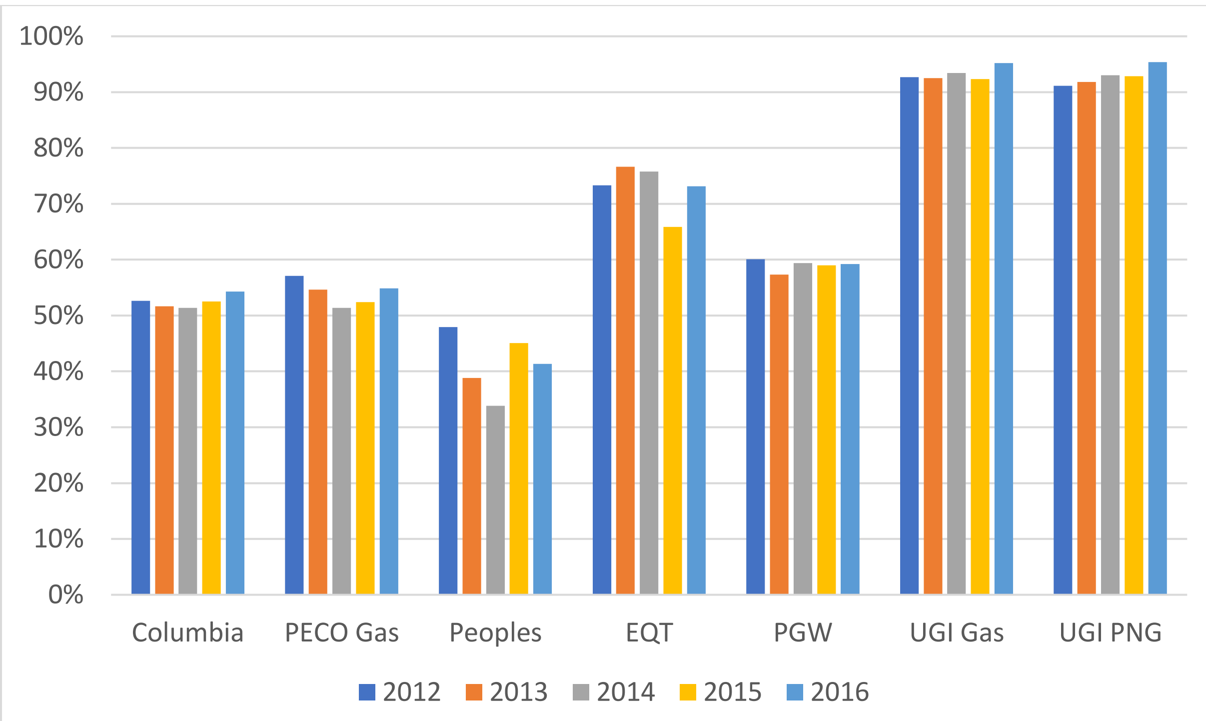
NGDC Percent of CAP Bills Paid

Table 6-1
Percentage of NGDC CAP Bills Paid In-Full



The data depicted in Table 6-1 above includes NGDC CAP customer billing information at all FPIG levels. From this data, it appears that CAP customers of UGI Gas and UGI PNG are the most reliable in paying their natural gas bills in-full. According to annual data submitted by UGI Gas and UGI PNG for the years 2012 to 2016, approximately 89 to 93% of CAP customer bills were paid. If this information is accurate, staff would expect to see lower in-program arrears accrued by UGI Gas and UGI PNG CAP customers, as the majority of the CAP bills should have been paid in full. According to Table 5-3, above, UGI Gas and UGI PNG CAP reported that their customers carried average in-program arrears exceeding $100 during the years 2012 to 2016. Based on the differences between these data points and that UGI Gas and UGI PNG's percentage of CAP bills paid is much higher than any other NGDC, there may be inconsistencies in how these utilities track the number of bills issued and the amount paid by CAP customers.

Table 6-2
Percentage of NGDC CAP Bills Paid In-Full
0-50% FPIG

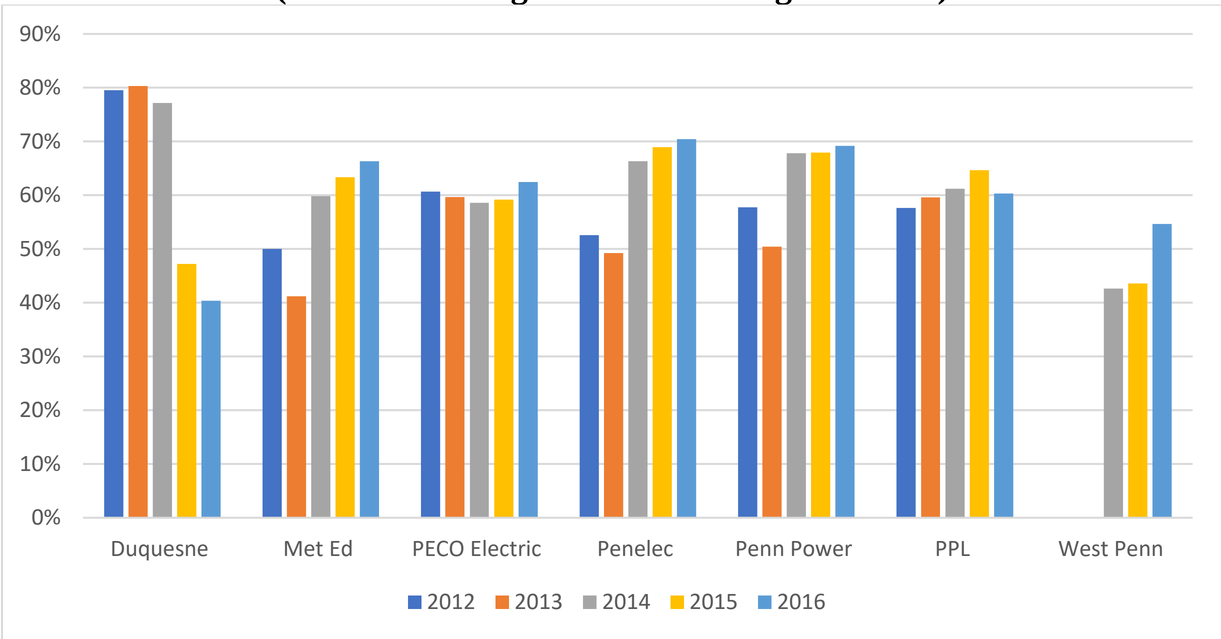


Staff also notes the differences in the percentage of bills paid by Peoples and Peoples Equitable CAP customers. Peoples and Peoples Equitable have maintained the same CAP requirements since at least 2015, including charging CAP customers 8% to 10% of their income or budget billing, whichever is less. Despite these commonalities, the two utilities reported different CAP customer payment behaviors. For example, while Peoples provided information that indicates that 57 to 71% of CAP bills were paid in-full during 2012-2016, Peoples Equitable reported that 69 to 75% of CAP bills were paid in-full during the same time period. The differences between the utilities are particularly noteworthy when one examines and compares their respective data for

CAP customers at or below the 0 to 50% FPIG level. *See* Table 6-2. While Peoples Equitable reported that 65 to 76% of CAP bills for customers at the 0 to 50% FPIG level were paid in-full during 2012-2016, Peoples reported that only 33 to 47% of its CAP bills at this income level were paid in-full. These variances between Peoples and Peoples Equitable may merit additional evaluation.

EDC Percent of CAP Bills Paid

Table 6-3
Percentage of EDC CAP Bills Paid In-Full
(Electric Heating and Non-Heating Accounts)



The information displayed in Table 6-3 includes 2012-2016 EDC CAP customer billing data aggregated from all FPIG levels, as well as by account status, including electric heating and electric non-heating accounts. Notable in this data is the information submitted by Duquesne, which indicates a dramatic decrease in the number of CAP customer bills paid in-full. From a high of nearly 80% in 2012 and 2013, the utility reported that only 40% of CAP customers' bills were paid in full in 2016. While this seemingly substantial decrease may be alarming, it is likely attributable to the changes that the utility implemented to its billing system in November 2014, resulting in higher monthly CAP bills in 2015 and 2016 due to budget bill corrections. *See* Footnote 29.

Aside from the information provided by Duquesne, the data in Table 6-3 nevertheless still shows marked annual and EDC variability, ranging from a low of 40% to a high of 70% of EDC CAP customer bills paid in-full. PECO and PPL appear to have the least variability over the same time frame.

Table 6-4
Percentage of EDC CAP Bills Paid In-Full
(Electric Heating Accounts)

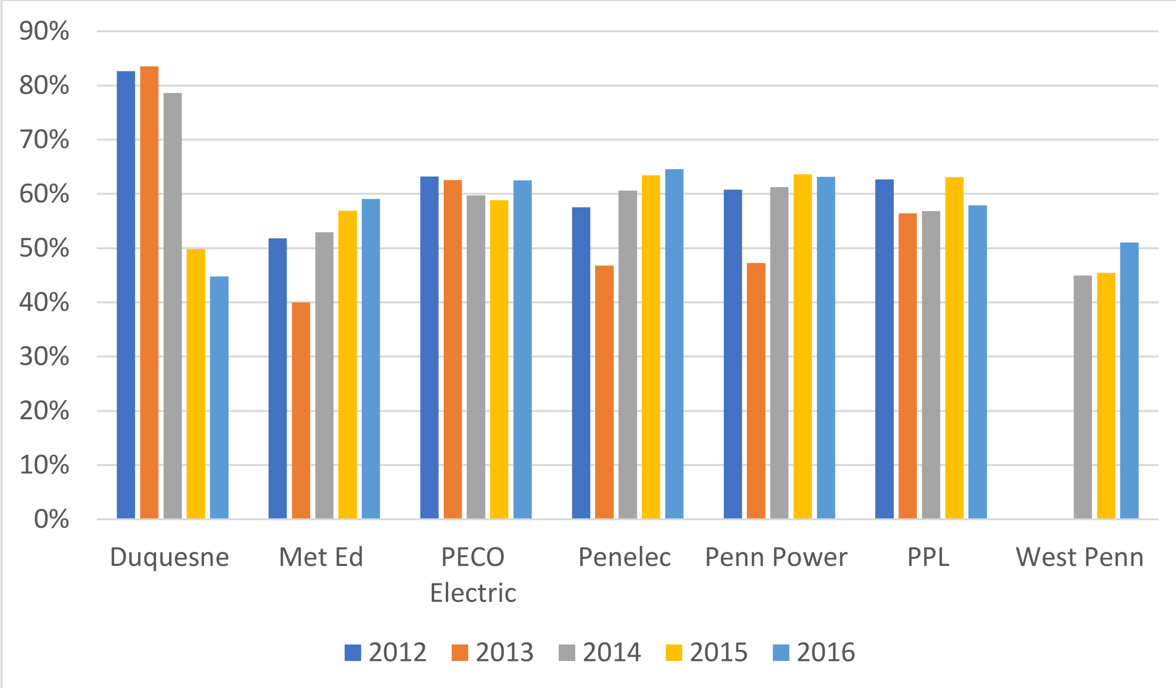


Table 6-5
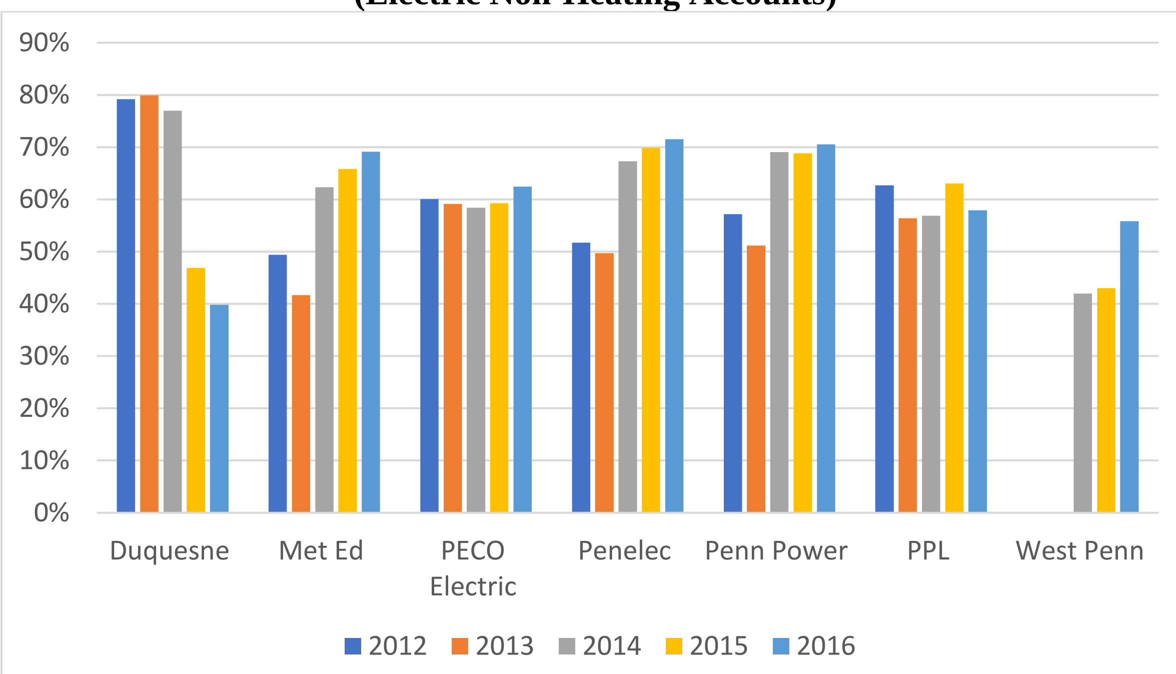
Percentage of EDC CAP Bills Paid In-Full
(Electric Non-Heating Accounts)



In Tables 6-4 and 6-5 above, the data show some variability between the percentage of CAP electric heating bills paid in-full compared to the percentage of CAP electric non-heating bills paid in-full. While seemingly negligible, there are differences, such as electric heating generally being more expensive than gas heating, that could indicate why a greater percentage of CAP electric non-heating bills were paid in-full compared to the percentage of CAP electric heating bills. This variability warrants further scrutiny and examination.

CAP Customer Billing Data by FPIG Level

Staff also examined the percentage of NGDC and EDC CAP customer bills paid at the 0 to 50%, 51 to 100%, and 101 to 150% FPIG levels. This analysis was conducted to determine if the increased income for CAP customers positively influences the percentage of utility bills paid in-full.

NGDCs

Table 6-6
Percentage of NGDC CAP Bills Paid In-Full
(0-50% FPIG Level)

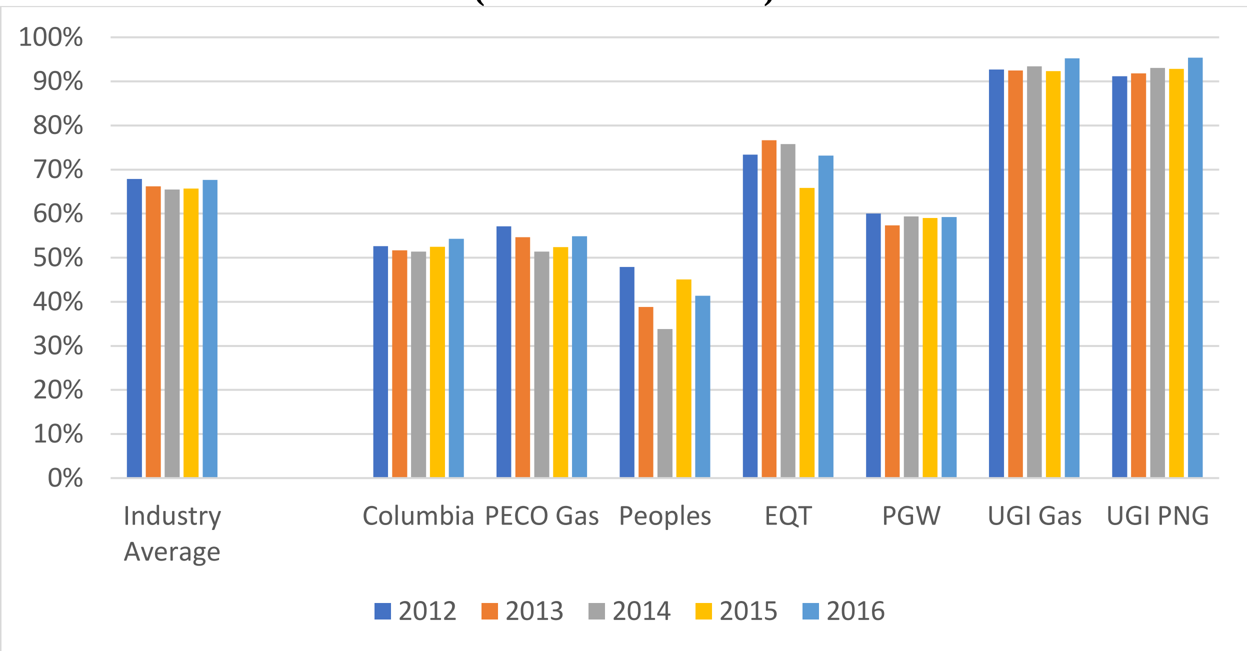


Table 6-7
Percentage of NGDC CAP Bills Paid In-Full
(51-100% FPIG Level)

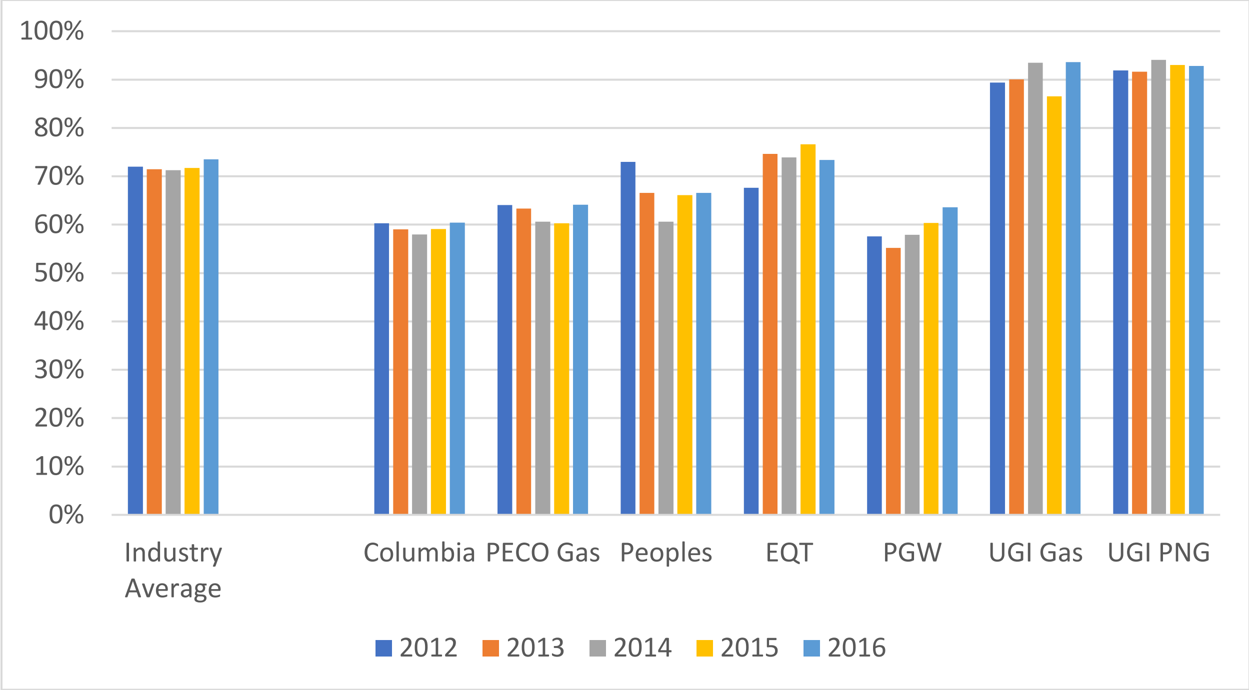

Table 6-8
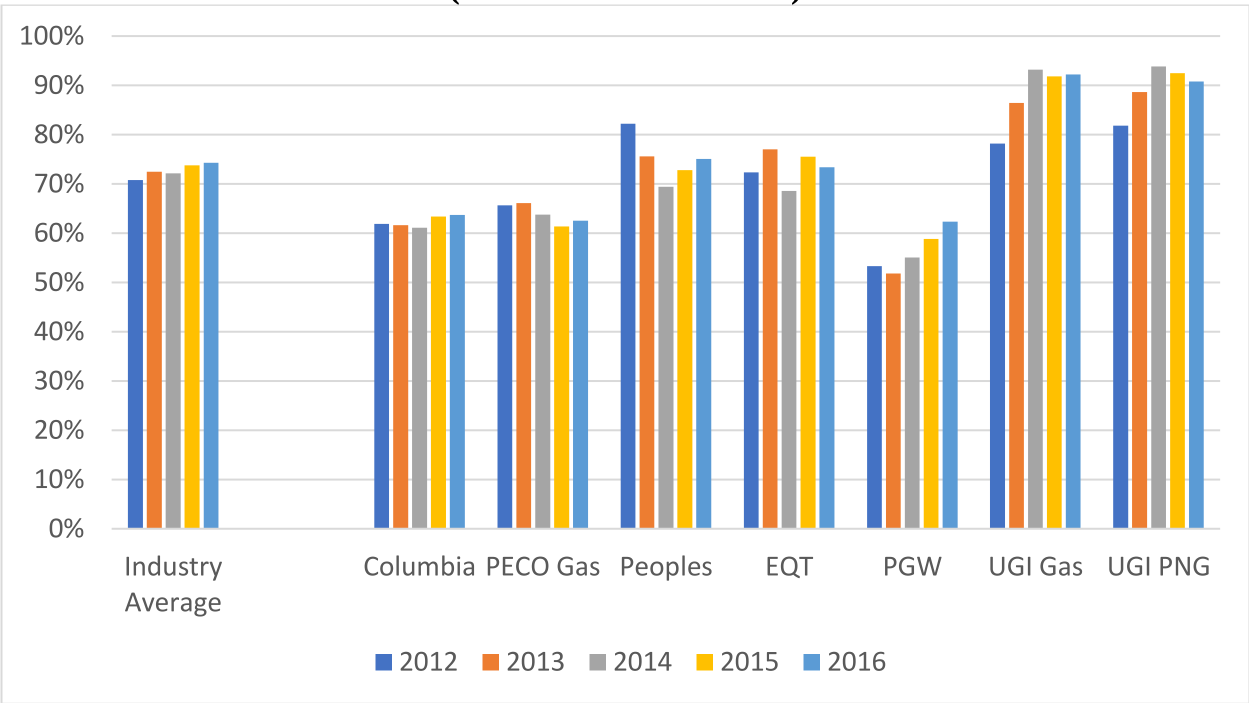
Percentage of NGDC CAP Bills Paid In-Full
(101-150% FPIG Level)



Tables 6-6, 6-7, and 6-8 include the percent of CAP bills paid for each utility as well as the weighted industry average for CAP NGDC customers at the different FPIG levels (i.e., 0 to 50%, 51 to 100%, and 101 to 150%) for the period 2012-2016. According to the data shown in Table 6-6, approximately 70% of NGDC CAP bills of customers at the 0 to 50% FPIG level were paid in-full. In examining annual data for each NGDC, the range of NGDC CAP bills paid in-full ranged from a low of 33% to a high of 95%.

In contrast, as seen in Table 6-7, a greater percentage of NGDC CAP bills of customers at the 51 to 100% and 101 to 150% FPIG levels were paid in-full; however, the differences appear to be negligible. Nevertheless, it is particularly noteworthy that several NGDCs showed that a lesser percentage of bills were paid in-full by CAP customers at the 101 to 150% FPIG level in comparison to the percentage of CAP bills paid by customers at the 51 to 100% FPIG level. Thus, the extent to which household income impacts or influences the percent of NGDC CAP utility bills paid in-full is unclear. *See* Table 6-8.

EDCs

Table 6-9
Percentage of EDC CAP Heating Bills Paid In-Full
0-50% FPIG Level

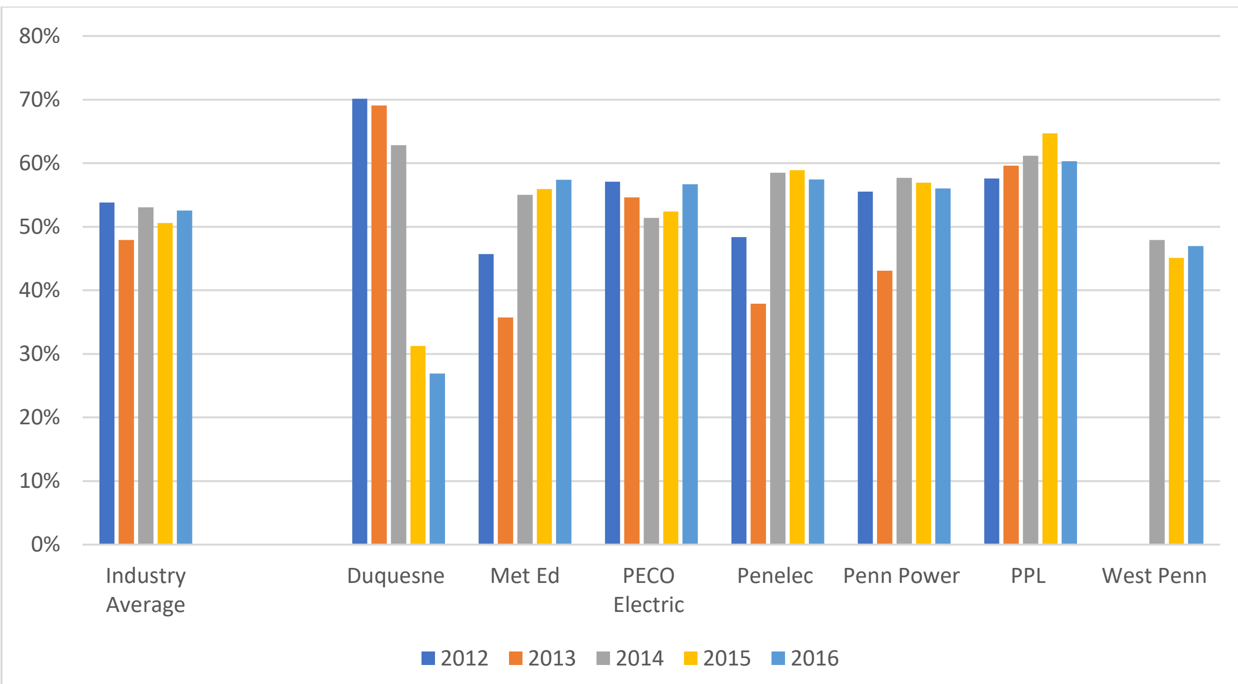


Table 6-10
Percentage of EDC CAP Heating Bills Paid In-Full
(51-100% FPIG Level)

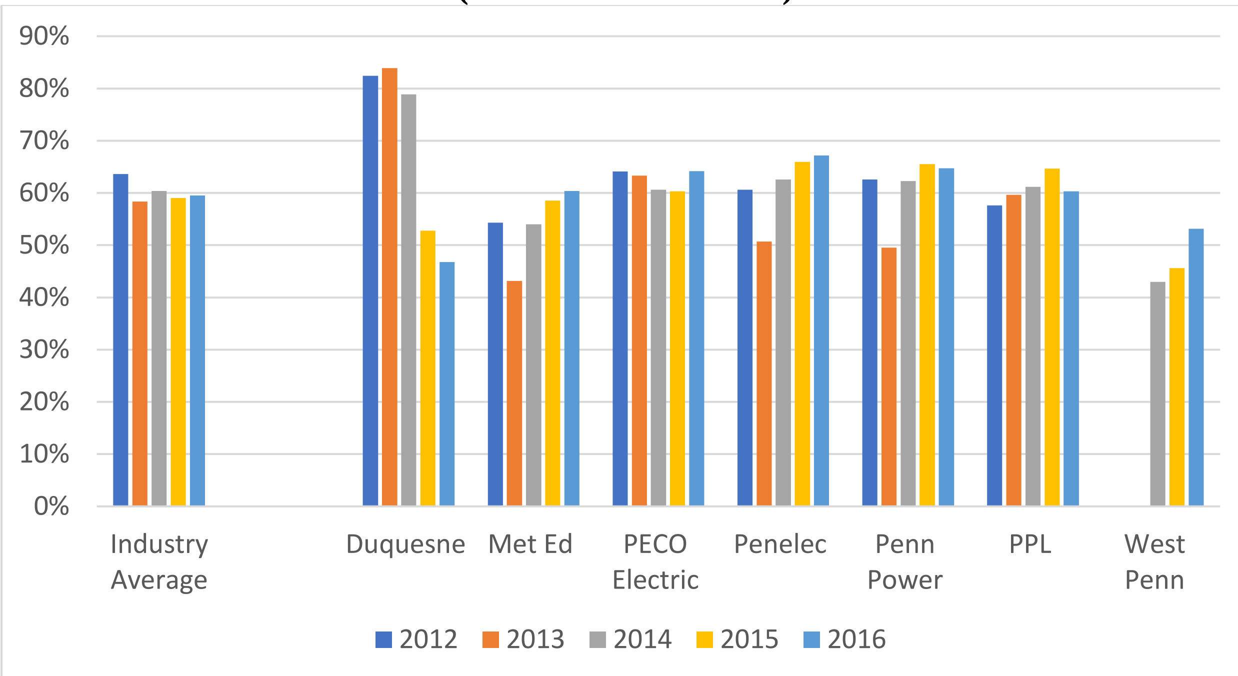

Table 6-11
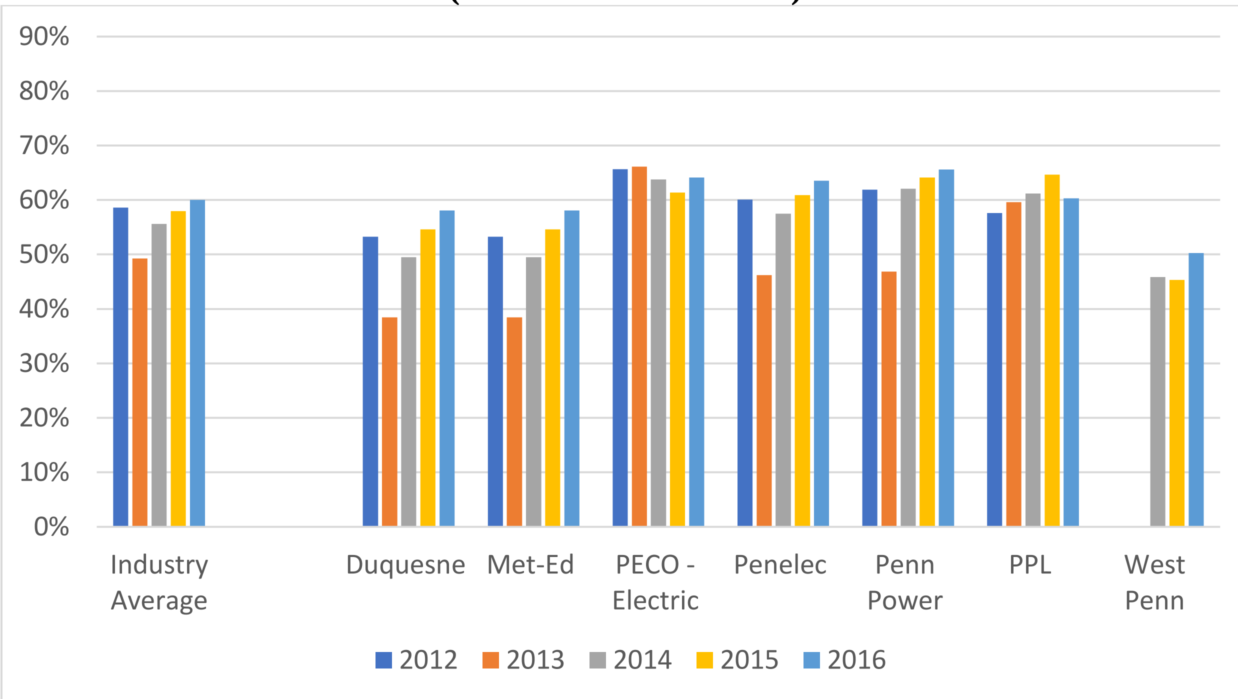
Percentage of EDC CAP Heating Bills Paid
(101-150% FPIG Level)



Tables 6-9, 6-10, and 6-11 include the percentage of CAP bills paid for each EDC as well as the weighted industry average for CAP electric heating customers at the different FPIG levels for the period 2012 to 2016.

While noticeable variability existed among EDCs, it appeared on average that approximately 50% of electric heating bills are paid by CAP customers at the 0% to 50% FPIG level. This contrasts markedly with the NGDC data, which showed that approximately 70% of bills were paid by CAP customers at the 0% to 50% FPIG level. This difference in the percentage of bills paid could be attributed to the lower price of natural gas in comparison to electricity; however, this point cannot be determined without additional information from the utilities.

In examining annual data for each EDC at the 0 to 50% FPIG level, most EDCs reported that at least 35 to 65% of electric heating bills were paid by CAP customers during this five-year period. Staff notes more variability within the time frame for each EDC than is seen in the industry average. Met-Ed, Penelec, and Penn Power had similar profiles, but the other EDCs display profiles that do not parallel the three FirstEnergy profiles or each other. The data do not provide any explanation for these regional differences or fluctuations.

In contrast, the data at the 51 to 100% and 101 to 150% FPIG levels indicated that a greater percentage of bills were paid by CAP electric heating customers at these FPIG levels in comparison to the percentage of bills paid by CAP electric heating customers at the 0 to 50% FPIG level. Based on weighted industry average data, approximately 60% of CAP bills were paid by CAP electric heating customers at the 51 to 100% and 101 to 150% FPIG levels. While this information showed a positive trend in payments made as household income increases, the increase in the percentage of CAP electric heating bills paid by customers at the 51 to 100% and 101 to 150% FPIG levels was nominal. Particularly noteworthy are the data provided by several EDCs that show *fewer* CAP electric heating customers at the 101 to 150% FPIG level paid their bills in comparison to the percentage of bills paid by CAP electric heating customers at the 51% to 100% FPIG level. Thus, the extent to which household income impacted or influenced the percent of EDC CAP utility bills paid in-full is unclear.

Observations

With the collection and assessment of the data noted above, several observations are offered:

- The billing system changes and upgrades of NGDCs and EDCs appeared to affect CAP monthly billing amounts and thus influenced whether utility bills were paid in-full.

- Some of the data submitted by the NGDCs and NGDCs in response to the data request for this report were inconsistent; therefore staff did not use it.

- Payment behavior of CAP customers did not appear to be strongly or definitively correlated to household income. This observation is particularly applicable to those CAP customers at the 51% to 100% and

101% to 150% FPIG levels where limited variability occurred in payment patterns between the two income levels. This pattern may indicate that other factors – beyond income – may have had an impact on whether CAP utility bills were regularly paid in full.

- At the 0% to 50% FPIG level, a higher percentage of NGDC CAP bills were paid in comparison to the percentage of EDC CAP bills paid at the same FPIG level. Given the low cost of natural gas compared to electricity, this observation may be indicative that the bills of NGDC CAP customers were more affordable in comparison to the bills of EDC CAP customers during this five-year study period; however, to conclusively determine this observation, additional data would need to be obtained from the utilities and evaluated.

VII. CAP Default Exit and Termination Rates

Objective

Evaluate the CAP default exit rates and CAP termination rates as possible affordability indicators to determine customer success in meeting the requirements of CAPs. Determine if a correlation exists between CAP default exit rates and CAP termination rates.

Background

CAP participants are required to, among other things, make timely and in-full monthly payments, allow access to meters, maintain or reduce consumption, participate in LIHEAP, and recertify eligibility information when requested. Failure to meet these program requirements can result in removal from CAP and/or loss of utility service.

The default exit rate is intended to track the number of customers who fail to meet the requirements of CAP. This definition of default exit rate includes all participants who were non-compliant with program requirements, including nonpayment, late payments, missed meter reads, excess consumption, failure to apply for energy assistance if required, and failure to recertify eligibility.[55] A higher default exit rate may indicate affordability issues or that the requirements of the program are not clearly or routinely communicated or understood by the household.

Households that are removed from CAP do not necessarily have their utility service terminated but are often left with debt that includes any non-forgiven PPA which become due as part of the balance when the customer is placed back onto full-tariff rates. Most utilities require customers to pay a balance to re-enroll in CAP. This balance may consist of a CAP catch-up amount (*i.e.*, any in-program arrears and the CAP billing price for the months spent out of the program). Other utilities require CAP customers to pay any in-program arrears and the full-tariff residential rates for any months spent out of the program. When former CAP customers are unable to re-enroll in CAP, pay their balance, or obtain a payment agreement, it can lead to service termination (*i.e.*, loss of utility service).

Service terminations for CAP households are usually a direct result of non-payment. Higher termination rates may indicate that CAP payments are unaffordable or may reflect strong enforcement of collection procedures to ensure customers do not accumulate high in-program arrears. Terminated CAP accounts – or accounts that are terminated after removal from CAP – may add to the amount of uncollectible balances if the customer cannot pay the outstanding balance to get back into CAP and is unable to obtain a payment agreement. In these situations, utility service is terminated, and the debt is eventually written off by utilities and recovered from non-CAP residential ratepayers.

[55] CAP customers who voluntarily leave the program are not counted in the default exit rate.

Methodology

Data regarding the number of CAP default exits are collected as part of the annual universal service and collections reporting (USR). The survey data request called for the number of CAP terminations. Staff anticipated that the number of CAP terminations would be a subset of the default exit number. The intent was to determine the relationship between those CAP customers who default from their CAP responsibilities and those CAP customers who have their service terminated.

To determine the CAP default exit and termination rates per year, the annual number of reported CAP default exits and CAP terminations were each divided by the average number of annual CAP enrollments. This allowed staff to compare these rates across the gas and electric utilities. *See* Appendix 9.C for average NGC and EDC CAP enrollments for 2012 through 2016.

Data Limitations - CAP Default Exits

Upon review of the CAP default exits as documented in the annual USRs and after consulting with several utilities, it became apparent that utilities were not consistently interpreting and reporting these data points. While some utilities counted each default occurrence as part of the default exits total, some utilities did not. Columbia, for example, reported that its system only tracked whether a customer has defaulted from CAP responsibilities during a calendar year (*e.g.*, yes or no). It did not count the number of individual instances a CAP customer was late on a payment or otherwise met the default exit definition. Thus, a Columbia CAP customer who was late with several payments and failed to recertify during a calendar year was only counted once in the utility's number of CAP default exits while other utilities would count each late payment and the failure to timely recertify as a separate occurrence of default exits. Due to the differences in how utilities tracked default exits, this data set could not be evaluated for comparison purposes. However, staff did observe some general trends from the data, as noted below.

Data Limitations - CAP Terminations

The data request called for CAP termination numbers to determine the extent of CAP default exits that eventually ended in termination of service. However, upon review of the reported data, it became apparent that there were inconsistencies in the way CAP terminations were reported. This, in part, appears to be due to the difficulty in determining when a CAP customer is "removed" from CAP versus when a CAP customer has service terminated. Some utilities removed CAP customers from the program but did not immediately terminate service. For example, Met-Ed, Penelec, Penn Power, PPL, and West Penn did not terminate service while a household is enrolled in CAP. Instead, they removed the household from the program if the household failed to meet its CAP payment responsibilities and would terminate service later. Thus, some utilities could only provide an estimate of the number of CAP customers who were removed from the program and subsequently had their service terminated.

In addition to the reporting inconsistencies, several utilities could not provide data due to system limitations. Specifically:

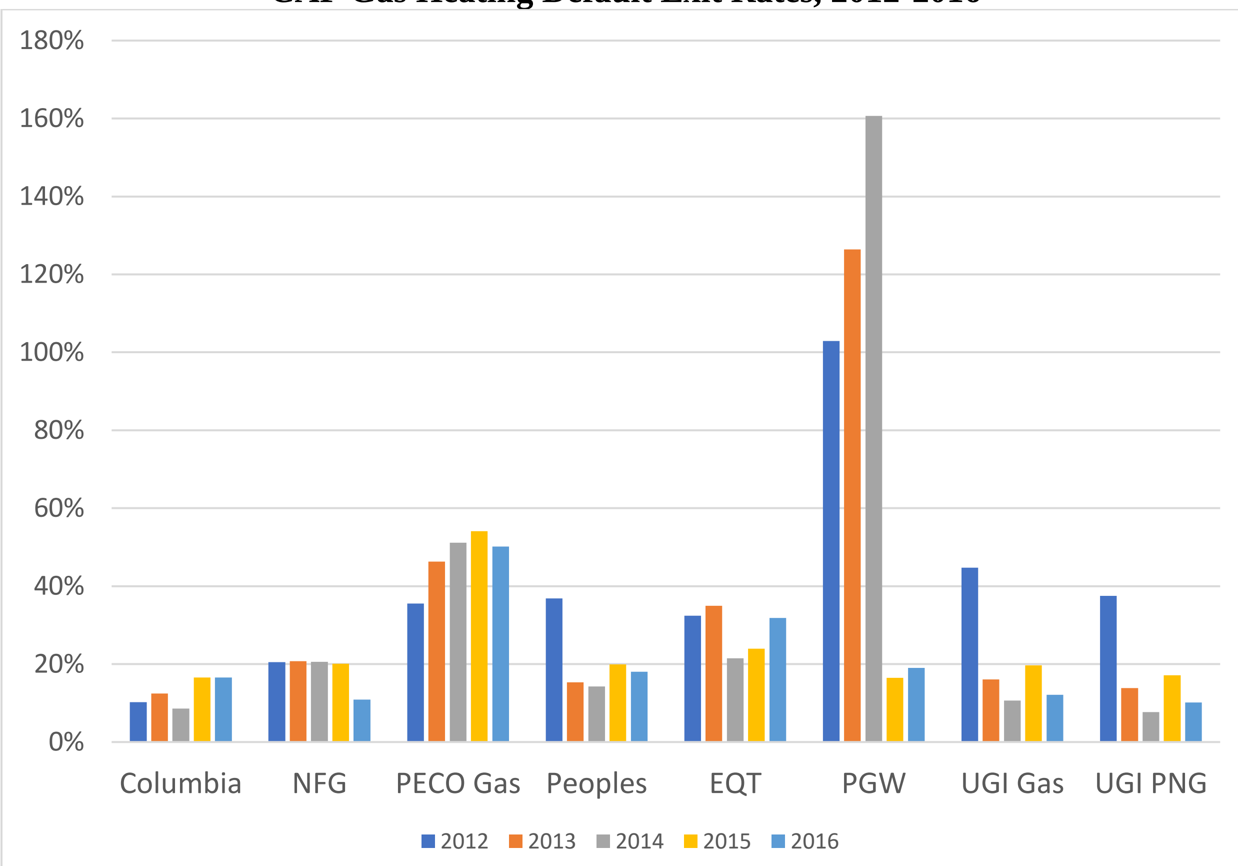
- Met-Ed, Penelec, Penn Power, and West Penn could not provide CAP termination data prior to 2014.

- Peoples Equitable could not provide CAP termination data prior to 2015.

Analysis

NGDCs – Default Exit and CAP Termination Rates

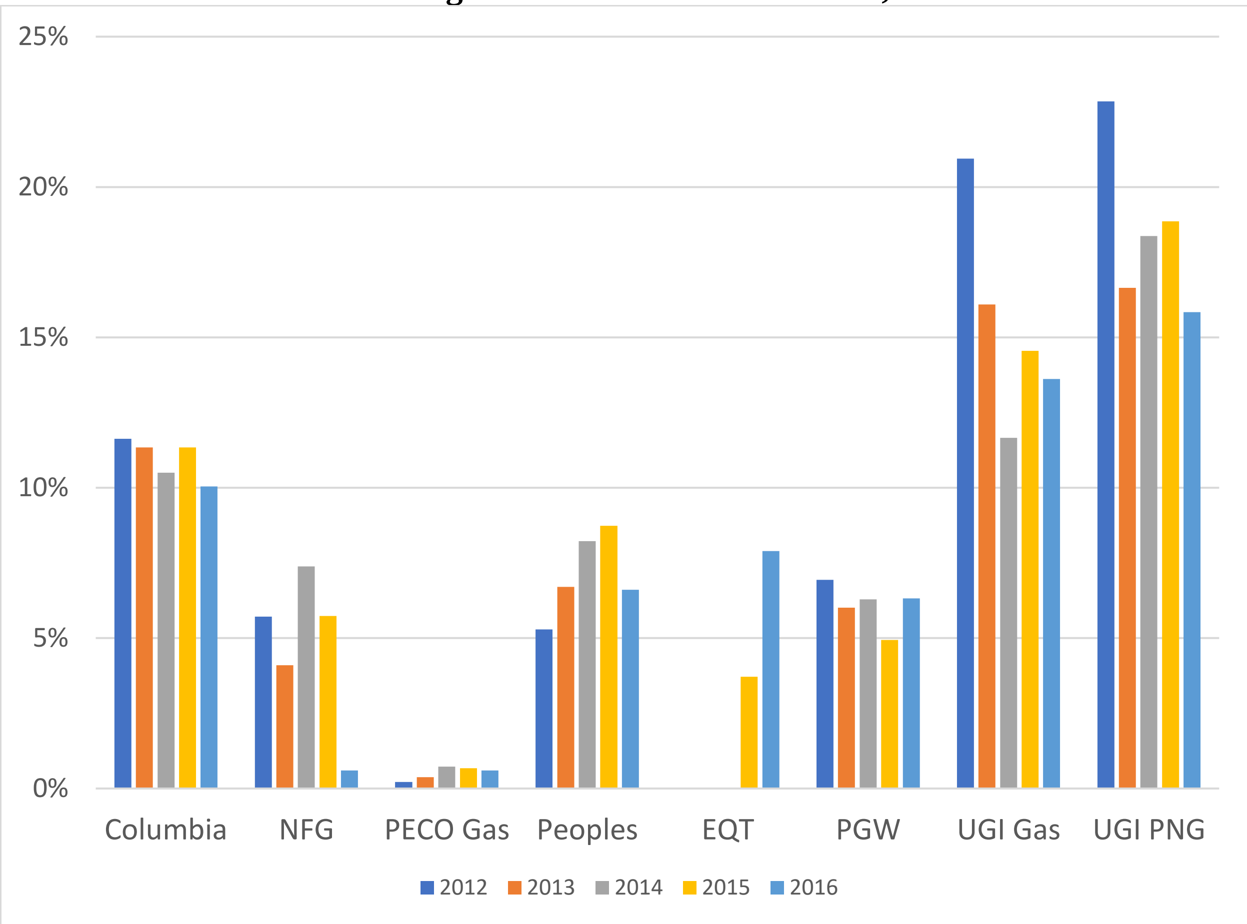
Table 7-1
CAP Gas Heating Default Exit Rates, 2012-2016



Despite the limitations of the reported CAP default exits and CAP termination data, there were some generalized observations that could be made. Table 7-1 shows PGW's default exit rates exceeded 100% of its average annual CAP enrollments from 2012 through 2014. The utility's default exit rate peaked at 161% in 2014 but dropped significantly to 16% and 19% in 2015 and 2016, respectively. PGW's 2015 and 2016 default exit levels were more consistent with the counts reported by other NGDCs.

Columbia reported three years (2012 to 2014) and UGI PNG reported four years (2013 to 2016) where their respective default exit rates exceeded their CAP termination rates; UGI Gas reported its CAP termination rate equaled its default exit rate in 2013 and exceeded this rate in 2016.[56]

Table 7-2
CAP Gas Heating Account Termination Rates, 2012-2016

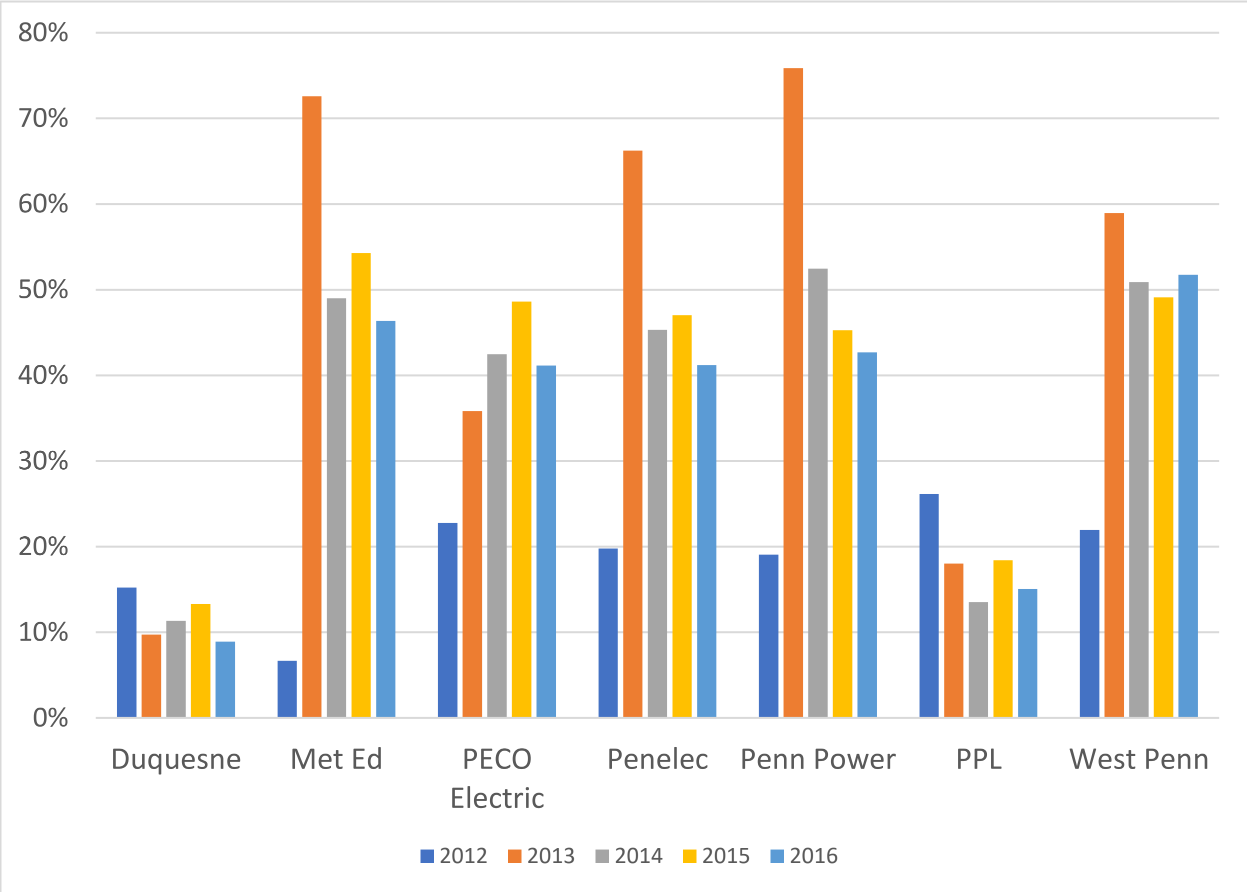


As seen in Table 7-2, UGI Gas and UGI PNG had the highest respective CAP termination rates during the study period, both peaking at 21% and 23% in 2012, respectively. Between 2013 and 2016, CAP termination rates ranged from 12% to 16% for UGI Gas and from 16% to 19% for UGI PNG. Columbia had relatively stable termination rates during this study period, ranging from 10% to 11% annually. Termination rates for half of the NGDCs ranged between 5% and 9%. PECO Gas reported the lowest termination rates, averaging less than 1% annually. This may have been the result of the previous PECO Gas practice (which is shared with PECO Electric) of offering payment arrangements on CAP arrears – instead of issuing termination notices – during this study period.[57]

[56] As explained in *Data Limitations* above, some utilities (*e.g.*, Columbia) do not count each instance of a customer defaulting from their CAP responsibilities. In these situations, the number of times a customer has service terminated could exceed their default exit count.
[57] See Footnote 46.

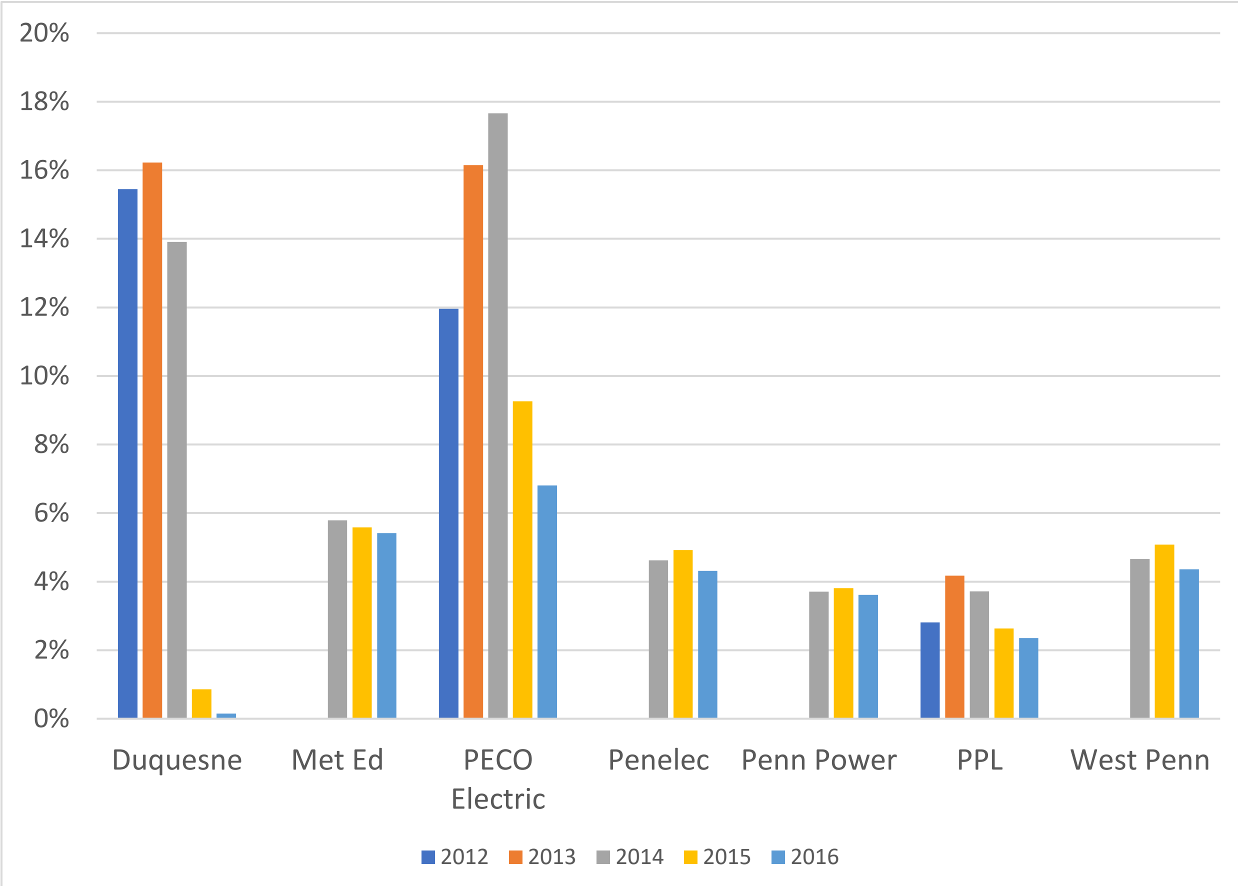
EDCs – Non-Heating Default Exit and CAP Termination Rates

Table 7-3
EDC Non-Heating CAP Default Exit Rates, 2012-2016



As seen in Table 7-3, the default exit rate for Met-Ed and Penelec peaked in 2013, exceeding 50%. However, both utilities' default exit rate declined below 40% for the last three years of this study, which is consistent with PECO Electric. Duquesne and PPL reported CAP default exit rates ranging between 10% to 20% for most years of this study.

Table 7-4
Electric Non-Heating CAP Account Termination Rates, 2012-2016



As seen in Table 7-4, the higher default exit rates reported by Met-Ed and Penelec did not translate into a higher rate of CAP terminations. Both utilities reported CAP termination rates between 4-6% for 2014 to 2016. Duquesne and PECO Electric reported higher CAP termination rates for electric non-heating accounts than other EDCs. Duquesne's termination rates ranged from 14% to 16% from 2012 through 2014 but dropped to less than 1% for 2015 and 2016. This decrease in terminations was likely due to Duquesne's CAP budget billing issues, which caused the utility to place a temporary hold on CAP terminations.[58] PECO Electric's CAP termination rates for non-heating accounts peaked at 18% in 2014 – during the polar vortex – but decreased to 9% and 7% in 2015 and 2016, respectively. Penn Power and PPL reported CAP termination rates of approximately 4% or less. Staff also note a slight increase in CAP terminations for many utilities in 2014, which may be the result of higher usage during the polar vortex.

[58] See Footnote 29.

EDCs – Heating Default Exits and CAP Termination Rates

Table 7-5
EDC Heating CAP Default Exit Rates, 2012-2016

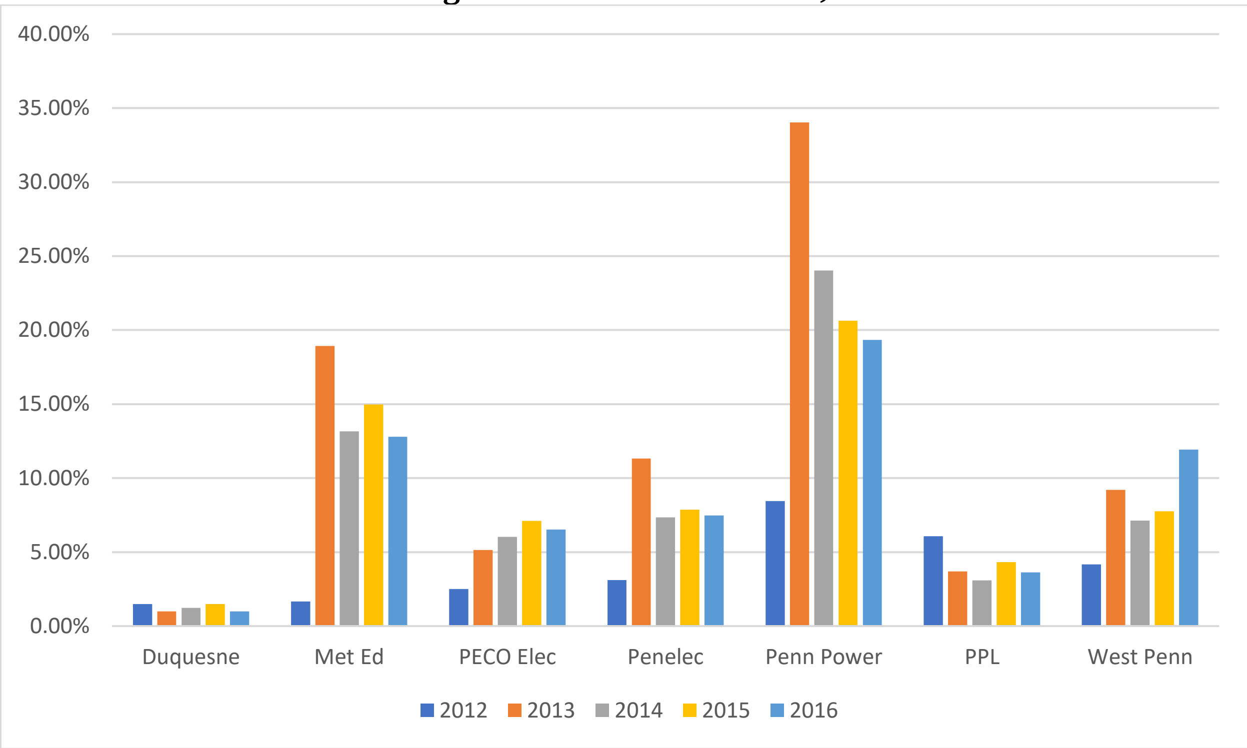


Table 7-5 shows the default exit rates for EDC heating CAP customers. Duquesne reported the lowest default exit rate for these customers at 1% to 2% for the entire five-year period. PECO Electric and Penelec reported default exit rates that ranged between 3% to 7% and 3% to 11%, respectively, for the five-year period. Penn Power reported the highest default exit rate for electric heating CAP customers, peaking at 34% in 2013. However, Penn Power's default exit rate dropped each subsequent year, declining to 19% by 2016.

Table 7-6
Electric Heating CAP Account Termination Rates, 2012-2016

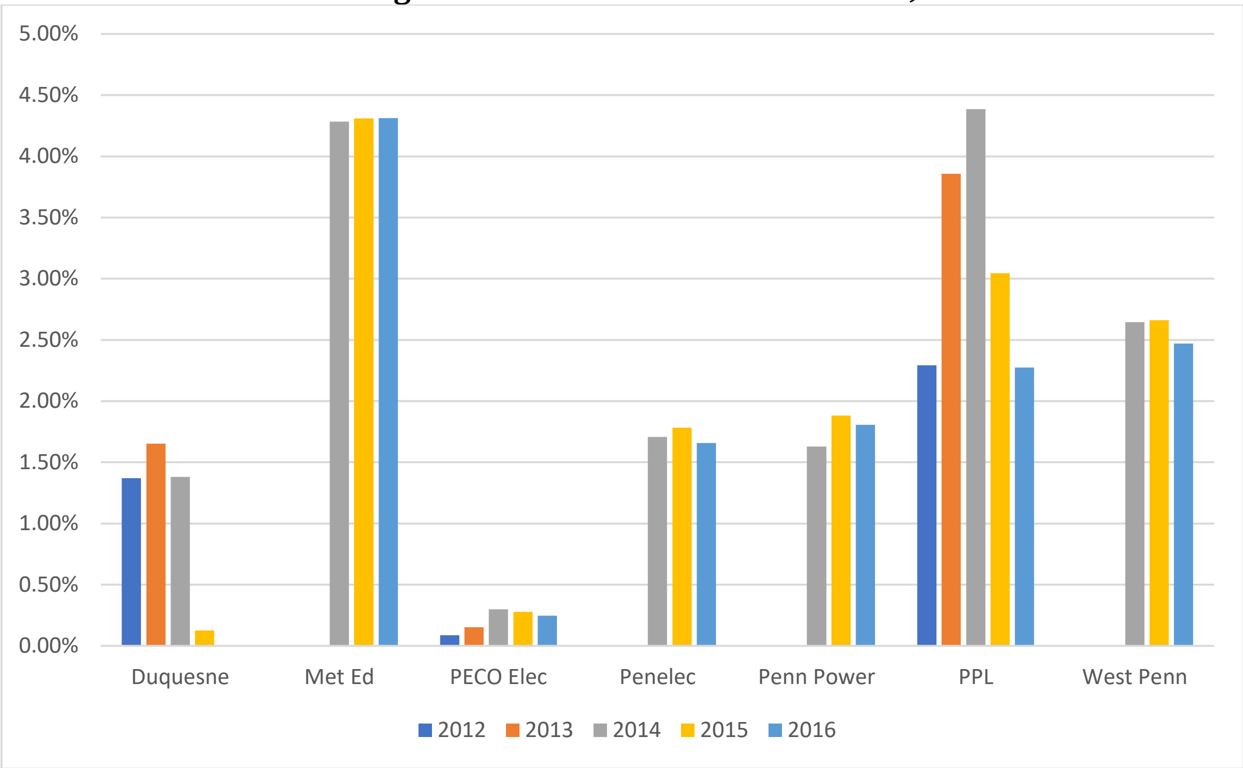

Table 7-6 shows the CAP termination rates for EDC heating CAP customers. Met-Ed had an average termination rate of approximately 4% for electric heating accounts for 2014 to 2016, which is higher than the termination rates for the other FirstEnergy utilities during this time period. West Penn had an average termination rate of less than 3%; Penelec and Penn Power had an average termination rate of less than 2%. This suggests that other factors, besides Met-Ed's CAP design, may have contributed to the higher number of terminations. More than half of the EDCs reported CAP terminations rates of less than 2% for heating customers. PECO Electric's CAP termination rate for electric heating accounts was less than 0.5% for all five years of this study. PECO Electric's low termination rates for CAP heating accounts may be attributable to (1) the utility's previous practice of offering payment agreements on in-program arrears and (2) approximately 80% of PECO Electric CAP customers were non-heating during this time period.[59]

Observations

Given the apparent inconsistencies between how utilities define and track default exits and CAP terminations, staff was unable to compare these data points among utilities or to confidently establish a correlation.

---

[59] *See* Table 3-2.

Not all customer removals from CAP resulted in service termination, but utilities were and are currently unable to provide the data to gauge to what extent this has occurred.

Higher CAP terminations for EDC non-heating CAP accounts in 2014 were likely the result of higher usage and/or higher bills during the polar vortex.

Differences between the EDC CAP heating termination rates for Met-Ed and the other FirstEnergy companies suggest that other factors – besides CAP design – contributed to a higher termination rates for CAP customers in the Met-Ed service territory.

VIII. Non-CAP Residential and Confirmed Low-Income Customer Debt

Objective

Determine if the percent of debt from confirmed-low income (CLI) customers is an indicator of CAP customer affordability.

Background

Many factors affect the number of customers in debt, including customer income level and ability to pay, utility collection practices, utility termination practices, and the size of customer bills. Utility collection policies vary and therefore also influence the "overdue" or "in debt" categorization.

The USR categorizes the Residential Class of customers as either non-CAP residential or CAP customers. CLI customers are a subset of non-CAP residential ratepayers, comprising all non-CAP customers *identified* as low-income. These CLI customers are financially vulnerable and the most likely to be in debt. Most CLI households are verified through the customer's receipt of a LIHEAP grant, identified when enrolled in a universal service program, or determined during the course of making a payment agreement.

There are also factors beyond customer choice that determine whether a customer may or may not be on a payment agreement. If customers have defaulted on utility and Commission payment agreements and/or their debt consists of CAP (in-program) arrears, they may not qualify for further payment agreements.[60]

Debt that is on a payment agreement is considered active and is often easier to collect than debt not on a payment agreement. Uncollectible debt represents more risk for the utility and often leads to higher gross write-offs, which are recovered from non-CAP residential ratepayers.

Low-income customers who are removed from CAP are less likely to qualify for additional payment agreements, and their balances are more likely to be written off as uncollectible debt. Thus, the amount of CLI debt not on an agreement may indicate affordability issues within a utility's CAP.

[60] NGDCs and EDCs have discretion in offering payment agreements to customers, but each utility limits the number of payment agreements offered. A utility must offer a payment agreement for restoration or service if the customer has income at or below 300 of the FPIG and has not defaulted on two or more payment agreements. 52 Pa. Code Section 56.191(c)(2). The Commission may establish a payment agreement between the utility and the customer when there is a dispute between the parties. Section 1405(a). However, absent a change in income, a customer cannot receive a second or subsequent payment agreement from the Commission until the most recent one is satisfied. Section 1405(d). The Commission cannot establish a payment agreement on CAP (in-program) arrears. Section 1405(c).

Methodology

For USR reporting, two categories exist for customers overdue and/or in debt. The first includes customers who are on a payment agreement, and the second includes customers who are not on a payment agreement. Those on a payment agreement include customers on both utility and Commission-granted payment agreements.

Consistent with USR reporting, customers enrolled in a CAP have not been counted in this report as part of the number of customers in debt who are on a payment agreement or not on a payment agreement.

The amount of non-CAP residential and CLI debt is shown as a percentage of revenue and is calculated by dividing the total dollars owed for each category by the overall residential revenue of each utility. This is to allow comparison between utilities, regardless of the dollar amount of debt or revenues.

Data Limitations

Two factors affect the uniformity of the data reported regarding the number of overdue customers and the dollars in debt associated with those customers. First, utilities have used, and continue to use, different methods for determining when an account is overdue.

Utilities consider either the due date of the bill or the transmittal date of the bill to be day zero. The transmittal date is 20 days before the due date. For USR reporting and comparative purposes, utilities are requested to consider the due date as day zero and to report debt that is at least 30 days overdue.

Duquesne, Met-Ed, Penelec, Penn Power, West Penn, Columbia, Peoples Equitable, UGI Gas, and UGI PNG reported according to the method requested. The variance among the other EDCs and NGDCs showed a difference of no more than 20 days from that method. PECO Electric and Gas, PPL, Peoples, and PGW report debt that is 10 days old, meaning these utilities are overstating the debt compared to utilities that reported debt as 30 days overdue. NFG reports debt that is about 40 days old, meaning NFG is understating its debt relative to the other utilities. *See* Appendix 2 of the *2016 Report on Universal Service Programs and Collections Performance* (USR) for utility-specific information.[61]

The second factor affecting the arrearage data uniformity is the timing of when a utility moves a terminated or "discontinued" account from active status (included in the USR reporting) to inactive status (excluded from the USR reporting). Utility collection policies and accounting practices affected the timing. *See* Appendix 2 of the *2016* USR for company specific information.

[61] http://www.puc.pa.gov/General/publications_reports/pdf/EDC_NGDC_UniServ_Rpt2016.pdf

Analysis

Non-CAP Residential Debt on Agreement

Table 8-1
NGDC Residential Customers, Debt on Agreement as % of Revenues, 2012-2016

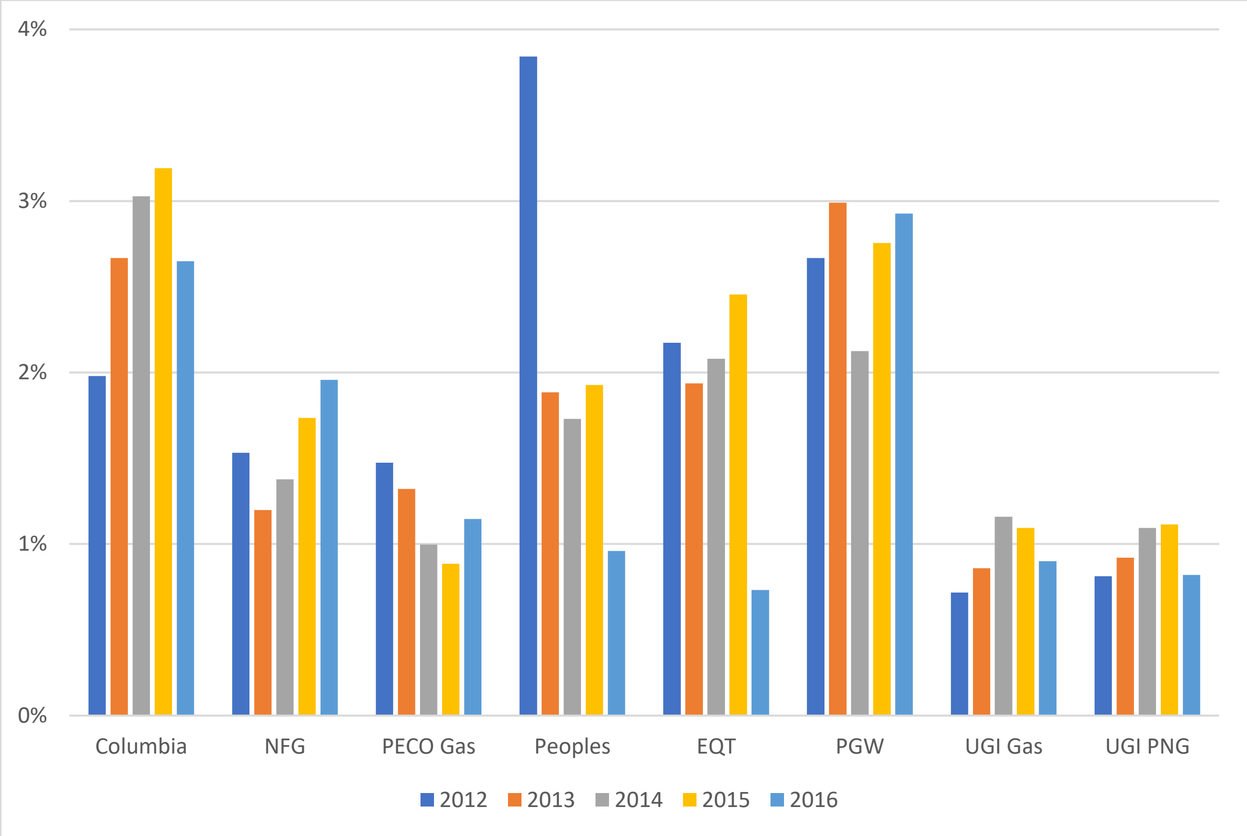

Table 8-2
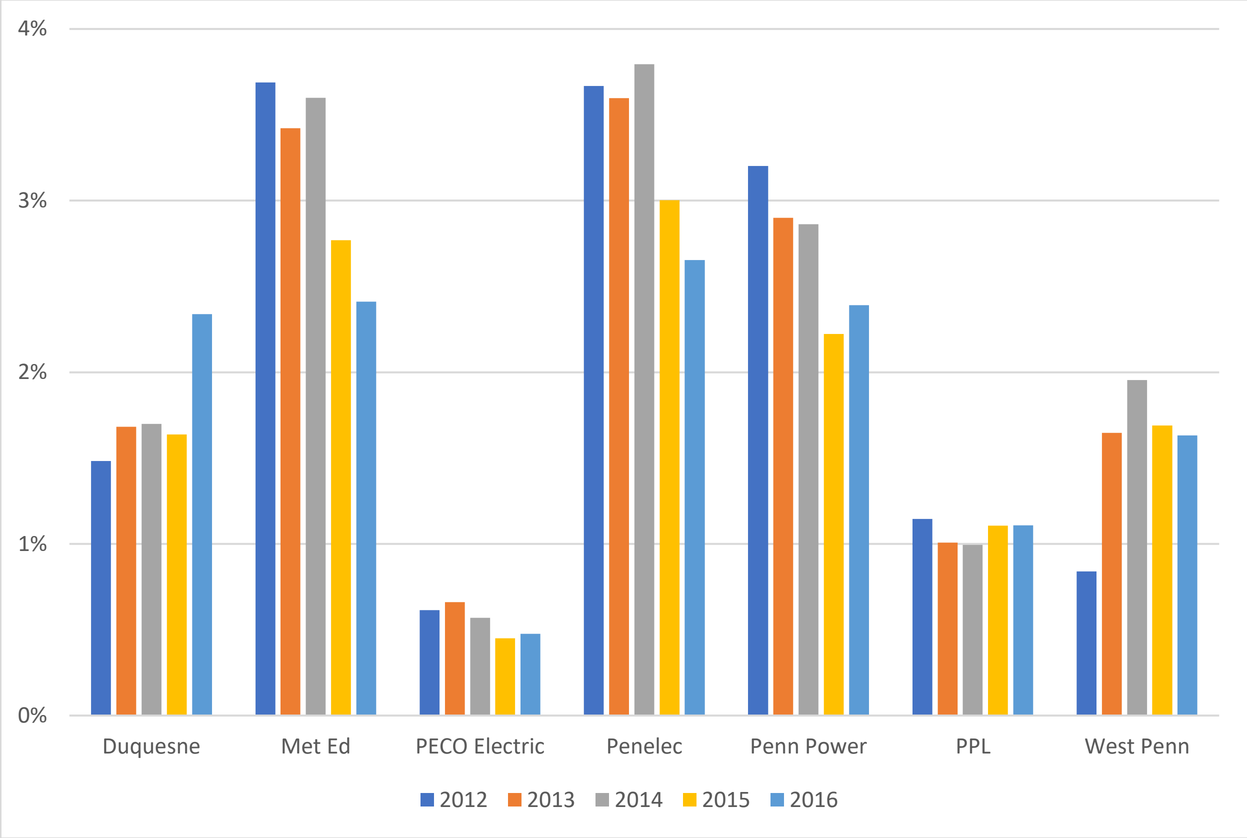
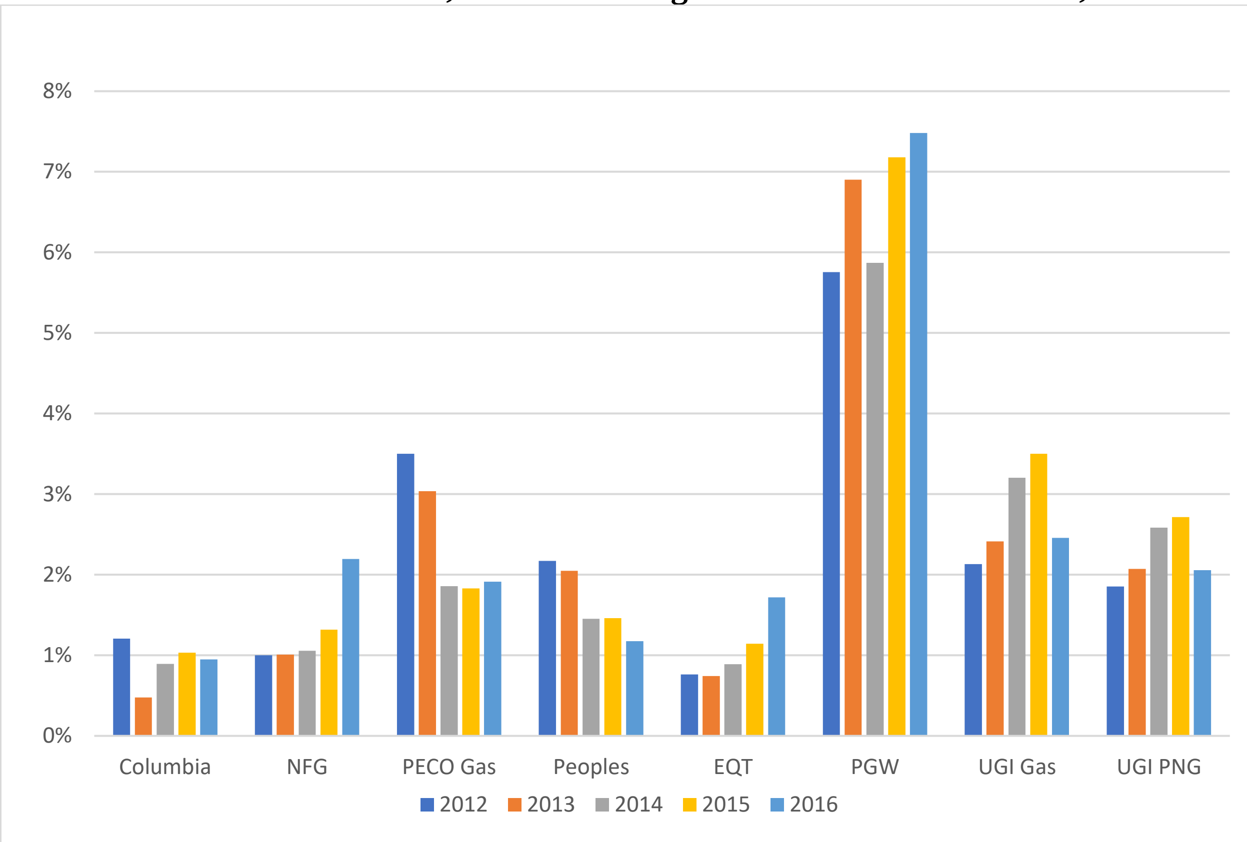
EDC Residential Customers, Debt on Agreement as % of Revenues, 2012-2016



As seen in Tables 8-1 and 8-2, most NGDCs reported their non-CAP residential debt on agreement comprised less than 2% of revenues. Columbia and PGW's non-CAP residential debt on agreement comprised 2% to 3% of their revenues. Non-CAP residential customer debt on agreement overall for EDCs was less than 3% of residential revenues. Peoples, Peoples Equitable, UGI Gas, and UGI PNG reported decreases in non-CAP residential customer debt on agreement in 2016.

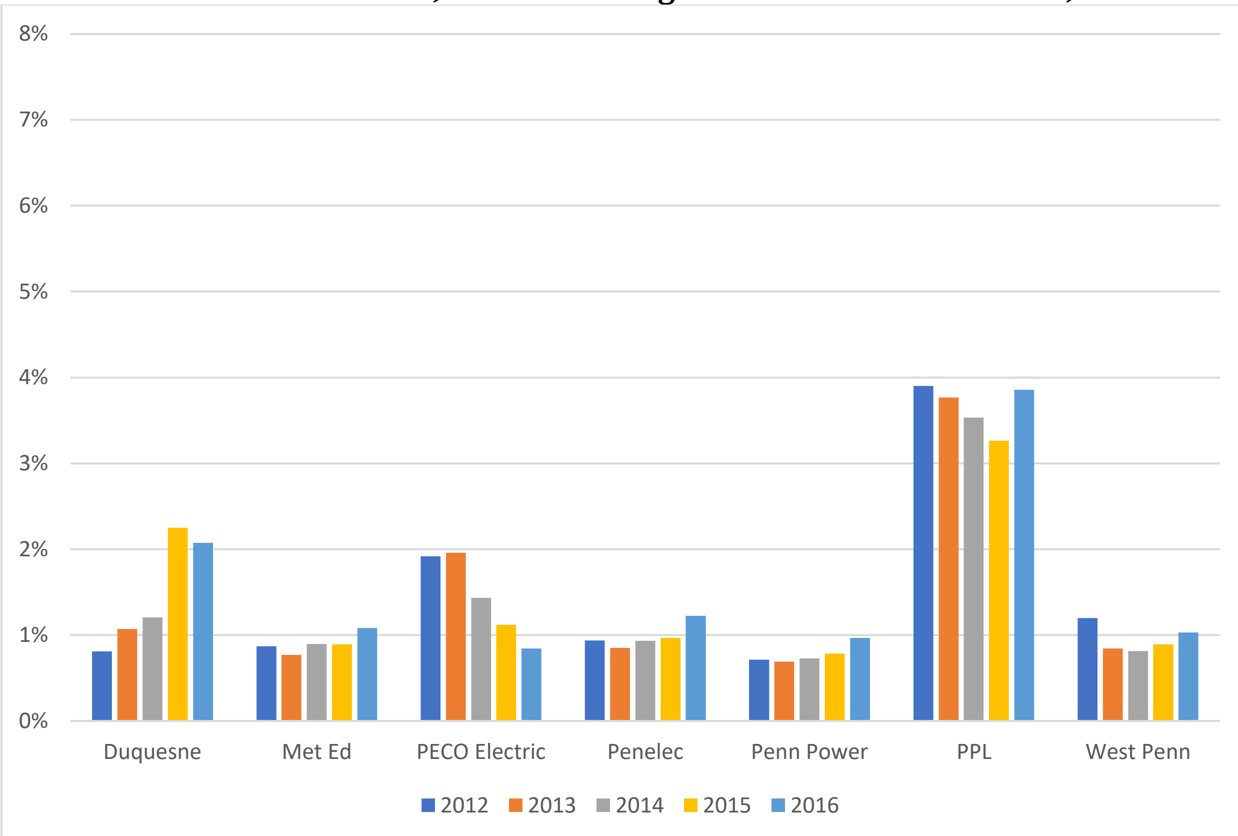
Residential Debt Not On Agreement

Table 8-3
NGDC Residential Customers, Debt not on Agreement as % of Revenues, 2012-2016



As seen in Table 8-3, half of NGDCs reported residential customer debt not on agreements comprised approximately 1% to 2% of their revenues. PECO Gas, UGI Gas, and UGI PNG averaged 2% to 3%, and PGW averaged 6% to 7% for this five-year period.

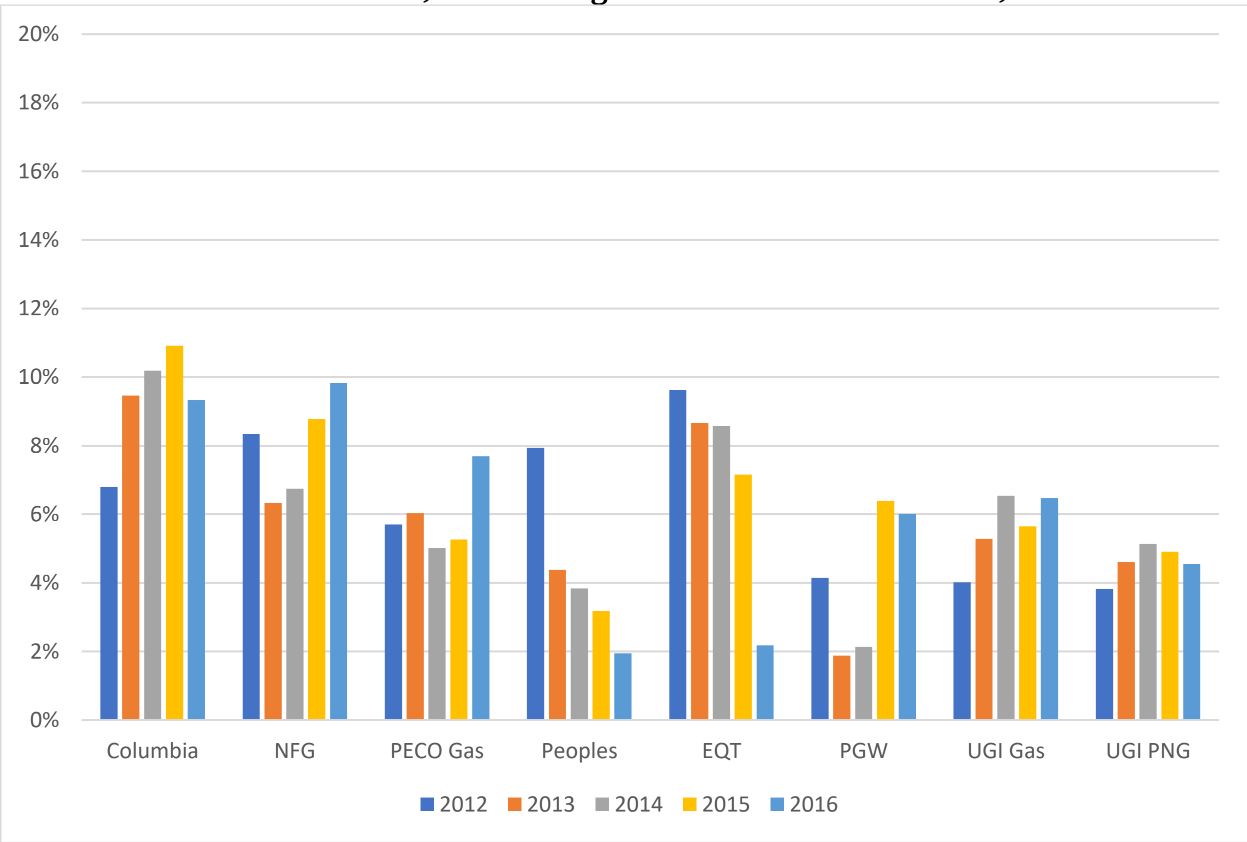
Table 8-4
EDC Residential Customers, Debt not on Agreement as % of Revenues, 2012-2016



As seen in Table 8-4, most EDCs reported that residential customer debt not on agreements comprised approximately 1% to 2% of their revenue. The debt not on agreement for Met-Ed, Penelec, Penn Power, and West Penn was 1% or less for the five-year period. PPL's residential debt not on agreement averaged 3% to 4% of revenue. Met-Ed, Penelec, Penn Power, and PPL reported an increase in residential debt not on agreement in 2016.

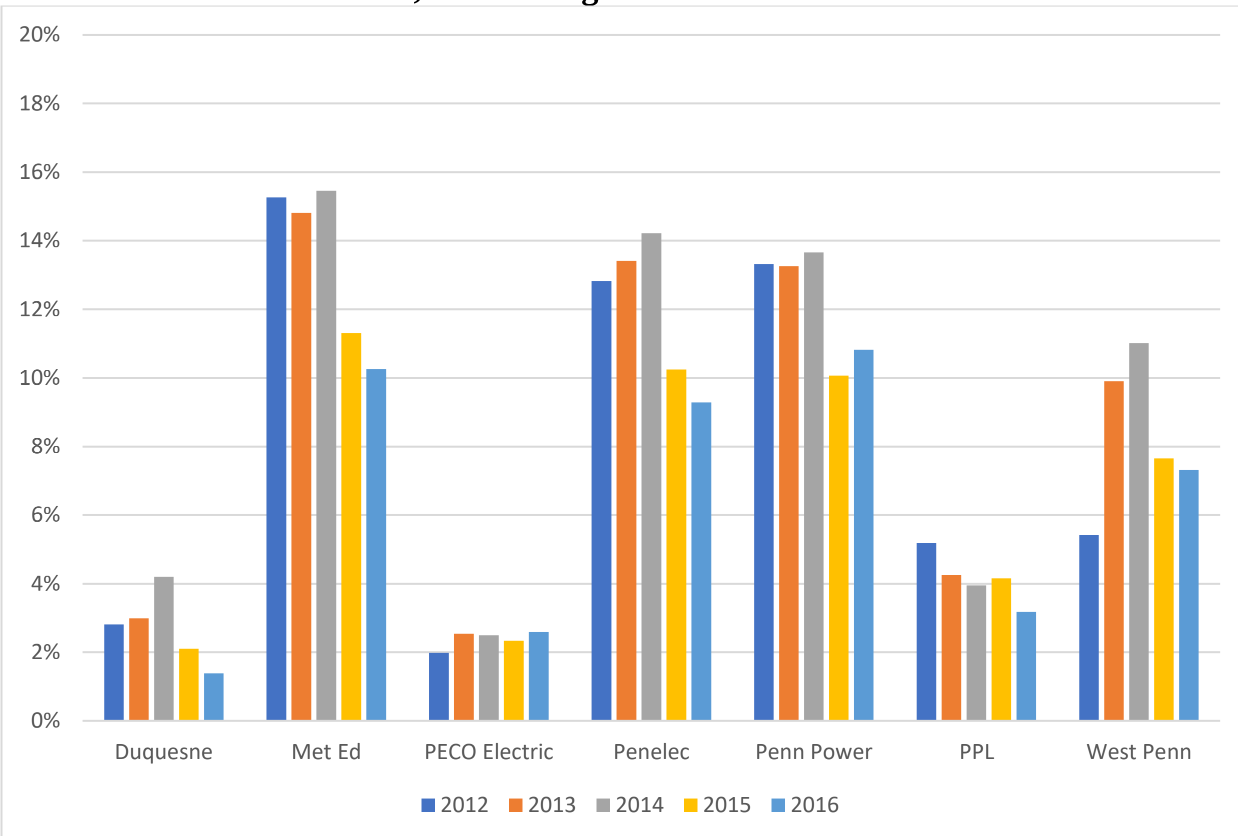
CLI Debt On Agreement

Table 8-5
NGDC CLI Customers, Debt on Agreement as % of Revenues, 2012-2016



As seen in Table 8-5, there appeared to be variability in the amount of CLI customer debt on agreement compared to revenue for NGDCs. Most NGDCs averaged between 4% and 10% of revenue during this five-year period. PGW and UGI Gas gradually increased the number of CLI customers on agreements, compared to revenue.

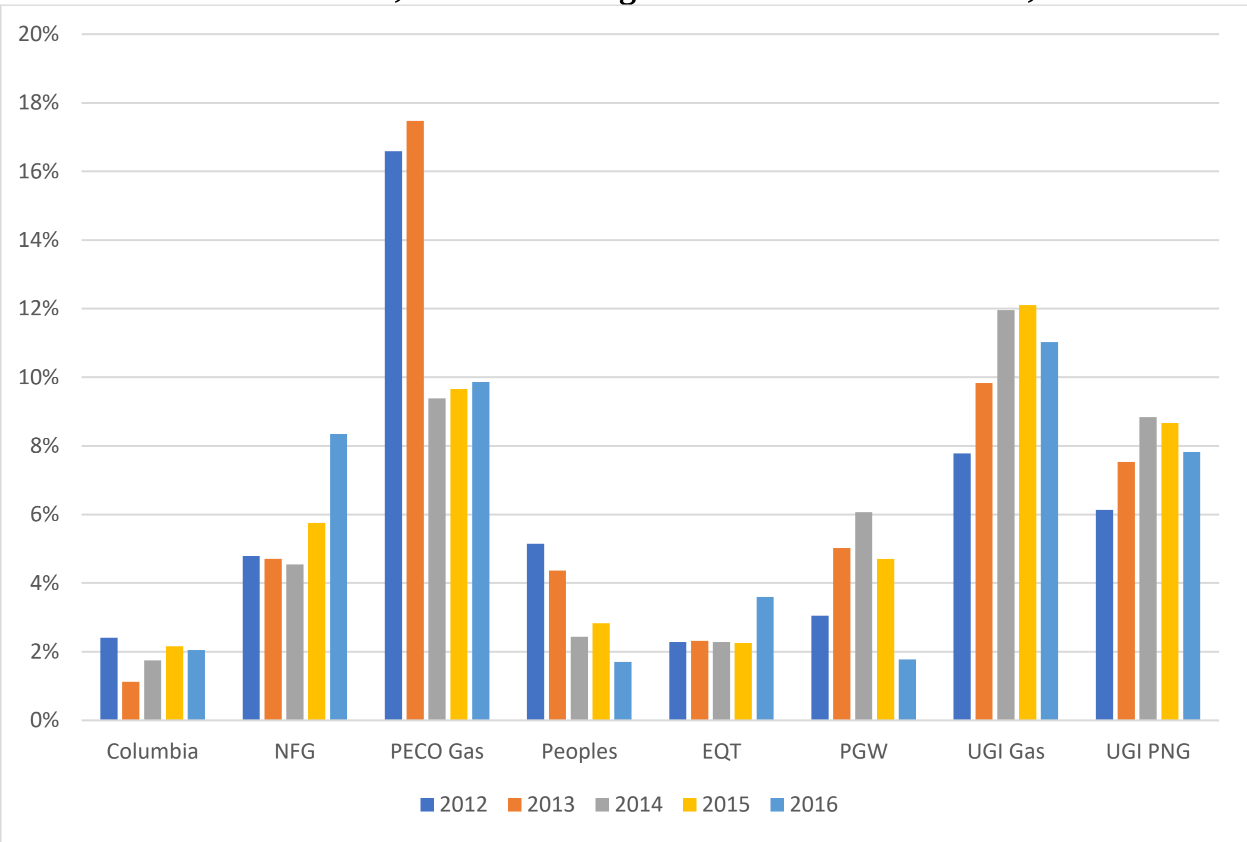
Table 8-6
EDC CLI Customers, Debt on Agreement as % of Revenues 2012-2016



As seen in Table 8-6, the amount of CLI customer debt on agreement compared to revenue also varied by EDC. Met-Ed, Penelec, Penn Power, and West Penn reported CLI debt on agreement as 2% to 3% of revenue. Duquesne's CLI debt on agreement fluctuated between 5% to 9% of revenue during this five-year period. PPL's reported CLI debt on agreement declined annually since 2012, from 17% in 2012 to 10% in 2016.

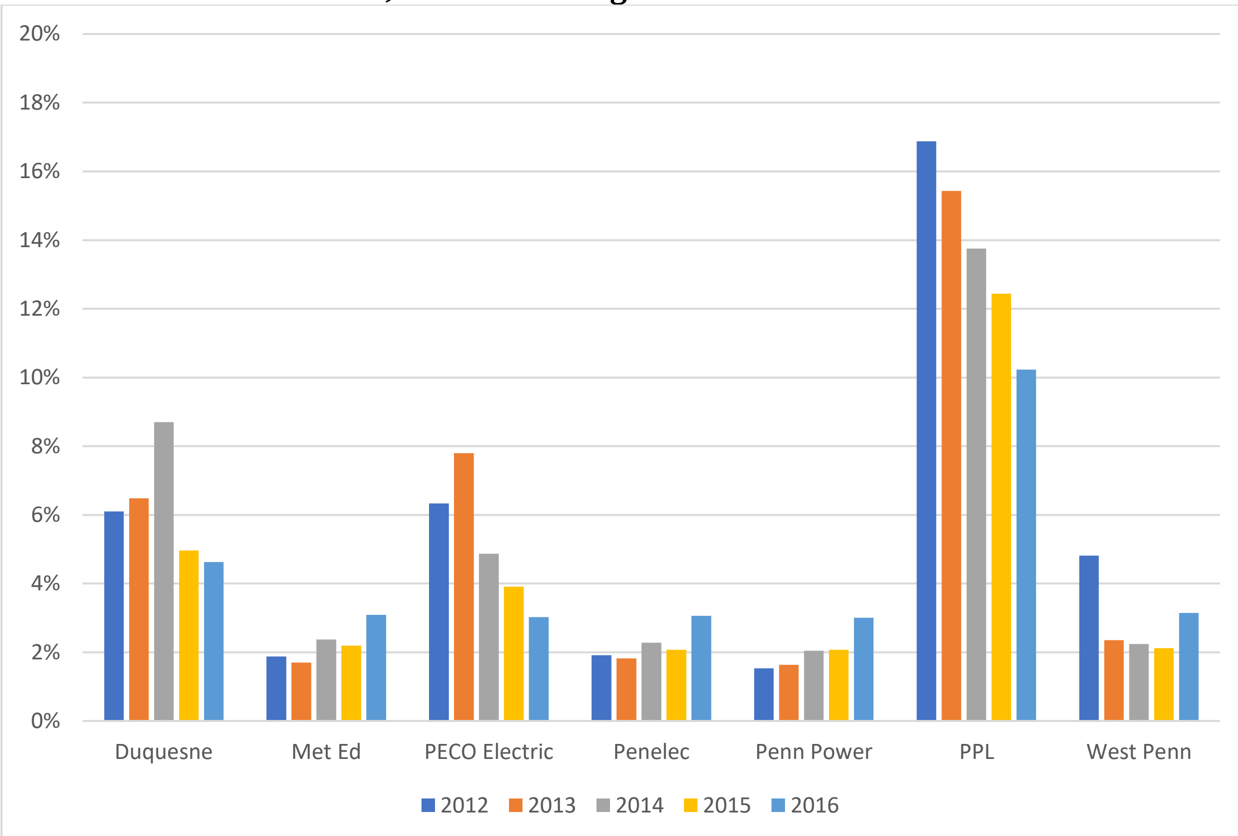
CLI Debt Not On Agreement

Table 8-7
NGDC CLI Customers, Debt not on Agreement as % of Revenues, 2012-2016



As seen in Table 8-7, about half of NGDCs reported their CLI debt not on agreement comprised approximately 2% to 4% of revenues. Columbia had the lowest amount, ranging from 1% to 2% during the five-year period. PECO Gas, UGI Gas, and UGI PNG had the highest amount. PECO Gas' CLI debt not on agreement exceeded 17% of revenue in 2013, but this percentage declined annually after that year; by 2016, the amount was less than 10%. This higher rate could be attributed to affordability issues within PECO Gas and Electric's CAP during this period. *See* Footnote 46. UGI Gas and UGI PNG also experienced increases in CLI debt not on agreement as compared to revenues from 2012-2015, but 2016 showed a decrease in this category for both companies.

Table 8-8
EDC CLI Customers, Debt not on Agreement as % of Revenues 2012-2016



As seen in Table 8-8, the amount of CLI debt not on agreement averaged 4% or less of revenues for most EDCs. PECO Electric and PPL generally reported gradual decreases for this category from 2012 to 2016. Based on a percent of revenue, PECO Electric's CLI debt not on agreement decreased from 6% to 2%, and PPL's decreased from 17% to 10% from 2012 to 2016. The FirstEnergy Companies (Met-Ed, Penelec, Penn Power, and West Penn) reported increases in CLI debt not on agreement in 2016.

Observations

About half of the NGDCs saw a decrease in residential debt on agreements in 2016. However, many of these utilities also saw a decrease in residential debt not on agreements. This could indicate an overall trend of decreasing residential debt carried by NGDC customers.

There did not appear to be a correlation between the different types of CAPs offered by utilities (*e.g.*, percent of income, rate discounts) and the number of CLI customers in debt not on agreement, as compared to income.

The general increases in the percent of CLI debt on agreements corresponded to a decline in the percent of CLI customers not on agreements for many utilities. This may indicate that utilities were having greater success in either enrolling CLI customers in CAPs or establishing payment agreements.

IX. Review of Other State Programs and Relevant Studies

Objective

To understand how other states and the District of Columbia (collectively, states) address energy burdens and affordability issues for their low-income residents and gather information from relevant independent studies.

Background

Pursuant to Commission direction in Docket No. M-2017-2587711, staff developed a survey to gather information on how other states address energy burdens and affordability issues for their low-income residents. The state survey covered an extensive array of factors. The state survey requested information on the jurisdictional utility regulatory low-income programs in each state and collected information on how the utilities treat the relevant variables in their own programs and policies. The state surveys were sent electronically to the various state utility commissions.

Staff worked with the Commission's CSIS Project to collect and collate the results of the state surveys and to review independent studies that may provide further insight into energy affordability issues.

Additionally, several published independent reports and studies were reviewed. Most of the independent reports and studies reviewed were performed by APPRISE[62] or by Fisher, Sheehan, and Colton. The CSIS Project assisted with the review of the published reports and studies.

Methodology

To determine which states most closely resemble Pennsylvania in terms of energy burden, FPIG levels, residential profiles, and other relevant factors, the Commission's CSIS Project collected the following U.S. Census data for each state:

- Urban/Rural population
- Age Distribution
- Education Level
- Fuel Type
- Household Size
- Poverty Status
- Retirement Population
- Substandard Housing

62 Applied Public Policy Research Institute for Study and Evaluation Inc. (APPRISE). www.appriseinc.org

Information was requested on 27 variables for the past five years. The data were combined into a rating system to calculate overall scores for each state. Seven states and the District of Columbia (D.C.) responded. Each respondent was then compared to Pennsylvania, with the highest possible comparison score being 27. The state most closely resembling Pennsylvania on these factors was Ohio, with a score of 14.

Data Limitations

No respondent answered every survey question. No respondent provided average energy burdens for low-income or non-low-income households or for heating/non-heating households for all five years.

None of the independent reports or studies reviewed considered all of the variables identified for this report. Several studies did, however, examine the relationship between subsets of the identified variables, as well as several studies that dealt with similar topics and had findings related to this study.

Analysis

Energy Burden Levels of Neighboring States

Although respondents to the survey did not provide average energy burden levels for their low-income and residential utility customers, each respondent provided valuable information about its own payment assistance programs.[63]

Information provided by Ohio, a state similar (and geographically close) to Pennsylvania, is of particular interest. Ohio has a mandated Percentage of Income Payment Plan (PIPP Plus)[64] which limits the amount spent on gas and electric service to 10% of the participating household's gross monthly income:

> Ohio's PIPP Plus is an extended payment arrangement that requires regulated gas and electric companies to accept payments based on a percentage of the household income for those customers who are at or below 150% of the federal income guidelines. The PIPP Plus payment amount is based on the household's countable income received during the previous 30 days. If a gas customer qualifies for PIPP Plus, he or she would pay 6% of the household's current gross monthly income to the gas company or a minimum of ten dollars, whichever is greater, year-round. If electricity is not the primary heat source, a customer pays 6% of the household's current gross monthly income to the electric company or a minimum of ten dollars, whichever is greater, year-round. The customer of

63 A summary of responses is included in Appendix 7.
64 *See* https://development.ohio.gov/is/is_pipp.htm for further information on Ohio's PIPP Plus.

an all-electric household pays 10% of the household's monthly income or a minimum of ten dollars, whichever is greater, year-round.

Ohio's 10% electric heating energy burden and its combined gas/electric energy burden are the highest levels compared to Pennsylvania's other neighboring states. The maximum energy burden for New York's payment assistance program is 6% for gas and electric service.[65, 66] New Jersey's maximum energy burden for its Universal Service Fund is also 6%.[67, 68] Maryland has an Electric Universal Service Program which provides an annual grant to reduce a low-income customer's budget bill amount based on household income and electric usage over the past 12 months.[69]

Pennsylvania's Home Energy Affordability Gap

Fisher, Sheehan, and Colton compile and publish annually a Home Energy Affordability Gap report for each state annually that reflects energy burden information for each state, using information from several sources, including the U.S. Census and the

---

[65] *See* New York Public Service Commission's *Order Adopting Low Income Program Modifications and Directing Utility Filings* at 3, Case 14-M-0565 (effective May 20, 2016). NOTE: New York also limited the budget for each utility's payment assistance program to 2% of revenues for sales to end-use customers. These costs are recovered from all ratepayer classes. May 20 Order at 3-4.

[66] The New York Public Service Commission favored a 6% energy burden level because it appears to be a widely accepted limit for utility payments:

> There is no universal measure of energy affordability; however, a widely accepted principle is that total shelter costs should not exceed 30% of income. For example, this percentage is often used by lenders to determine affordability of mortgage payments. It is further reasonable to expect that utility costs should not exceed 20% of shelter costs, leading to the conclusion that an affordable energy burden should be at or below 6% of household income (20% x 30% = 6%). A 6% energy burden is the target energy burden used for affordability programs in several states (e.g., New Jersey and Ohio), and thus appears to be reasonable. It also corresponds to what U.S. Energy Information Administration data reflects is the upper end of middle and upper income customer household energy burdens (generally in the range of 1 to 5%). The Commission therefore adopts a policy that an energy burden at or below 6% of household income shall be the target level for all low[-]income customers.

May 20 Order at 7-48.

[67] New Jersey requires USF customers to pay 3% for natural gas service, 3% for electric non-heating, and 6% for electric heating. The discount provided to customers is based on the difference between their annual utility bill (after LIHEAP is applied) and required percentage of household income. https://www.state.nj.us/dca/divisions/dhcr/faq/usf.html#q1

[68] Although not a neighboring state, Illinois also administers a PIP that charges customers a maximum of 6% of their income for gas and electric service. The maximum PIP credit is $150 per month or $1,800 annually. Illinois Senate Bill 1918 at 108-109. http://www.ilga.gov/legislation/96/SB/PDF/09600SB1918lv.pdf

[69] *See* http://dhr.maryland.gov/office-of-home-energy-programs/how-are-grants-determined/ for more information about the Maryland grants.

five-year American Community Survey (ACS).[70] Information is compiled for each county in a state which is then used to calculate an statewide energy burden value.[71] Additionally, Fisher, Sheehan and Colton report gross LIHEAP dollars, the number of households at or below 150 percent of the poverty level, and the number of heating/cooling bills covered by LIHEAP.

The energy burden levels in the Fisher, Sheehan, and Colton reports reflect the cost of various household energy sources (*e.g.*, natural gas, electric, propane, oil, coal, etc.). Thus, the energy burdens they calculate for Pennsylvania will not match precisely with the energy burdens reflected in this staff report.

Table 9-1
Energy Burden for Pennsylvania Households, 2012 to 2016[72]

	Energy Burden				
Poverty Level	**2012**	**2013**	**2014**	**2015**	**2016**
Below 50%	34%	33%	33%	30%	28%
50-100%	19%	18%	18%	16%	15%
100-125%	13%	12%	12%	11%	10%
125-150%	10%	10%	10%	9%	8%
150-185%	9%	8%	8%	7%	7%
185-200%	7%	7%	7%	7%	6%

Source: *Home Energy Affordability Gap, 2012-2016*

As seen in Table 9-1 above, Pennsylvania households with incomes at or below 50% of the FPIG had energy burden levels ranging from 34% in 2012 to 28% in 2016. Household with incomes between 50-100% and 100-150% had energy burdens ranging from 19% to 15% and from 10% to 8%, respectively, during this five-year period.

[70] Fisher, Sheehan & Colton. "Home Energy Affordability Gap," *Public Finance and General Economics*. Retrieved from http://www.homeenergyaffordabilitygap.com/index.html.
[71] Fisher, Sheehan & Colton explain the affordability gap as *actual home energy bills* minus *affordable home energy bills* (defined as 6% gross household income) equals the *home energy affordability gap* (calculated through segmenting each state's counties into FPIG sections).
[72] Includes households using various heating sources (*e.g.*, natural gas, electric, oil, propane, coal, wood, etc.). This is not restricted to jurisdictional gas and electric customers

Table 9-2
LIHEAP Allocation, Households Below Poverty Level, and Covered Bills for Pennsylvania, 2012-2016

	Gross LIHEAP Allocation (in millions)	# of Households ≤150% FPIG	Average Energy Bills "Covered" by LIHEAP
2012	$209,548	1,034,276	182,533
2013	$184,642	1,063,068	166,644
2014	$175,603	1,080,857	150,862
2015	$204,099	1,092,514	207,840
2016	$182,170	1,085,999	216,354

Source: *Home Energy Affordability Gap*, 2012-2016

Although there appeared to be a decrease in household energy burden levels from 2012 to 2016, the number of LIHEAP-income-eligible Pennsylvania households reportedly increased. Table 9-2 above shows that households with incomes at or below 150% of the FPIG increased from approximately 1 million in 2012 to approximately 1.1 million in 2016.

Table 9-3
Energy Burden for Pennsylvania and Similar States, 2016

Energy Burden 2016				
	Below 50%	50-100%	100-125%	125-150%
Pennsylvania	28%	15%	10%	8%
Ohio	29%	15%	10%	8%
Kansas	29%	16%	11%	9%
Michigan	33%	18%	12%	10%
Virginia	32%	17%	12%	9%
Missouri	27%	15%	10%	8%
Wisconsin	33%	17%	12%	10%
Rhode Island	36%	19%	13%	10%
Delaware	39%	21%	14%	11%
New York	32%	17%	11%	9%
West Virginia	31%	17%	11%	9%

Table 9-4
LIHEAP Allocation, Households Below Poverty Level, and Covered Bills for Pennsylvania and Similar States, 2016

	Gross LIHEAP Allocation (in millions)	# of Households below 150% FPIG	Heating/Cooling Bills "Covered" by LIHEAP
Pennsylvania	182,170	1,085,999	216,354
Ohio	131,709	1,142,393	181,919
Kansas	28,576	251,395	41,595
Michigan	140,599	995,442	155,015
Virginia	75,278	599,916	74,019
Missouri	65,662	602,511	101,018
Wisconsin	91,667	492,434	103,931
Rhode Island	23,271	91,177	23,365
Delaware	11,280	69,369	8,945
New York	325,976	1,790,231	373,826
West Virginia	25,927	213,221	25,798

Source: *Home Energy Affordability Gap*, 2012-2016

Of those states with similar energy burdens, none have demographic/energy profiles similar to Pennsylvania. However, Ohio is close, with identical energy burden for several poverty categories. Only six states, including Ohio and New York, had a greater number of households at or below 150% of the poverty level. As seen in Table 9-4 above, New York was the only state to receive a larger gross LIHEAP allocation in 2016, and only California (not shown) and New York covered a greater number of heating/cooling bills.

Examining all 50 states (plus the District of Columbia) reveals that Pennsylvania's average energy burdens for all energy sources were among the highest in the country for households below 150% of the poverty level.

Review of Other Relevant Studies

Several independent studies examined relationships between subsets of variables examined in this report. Other studies dealt with similar topics and had findings related to this report. These independent studies are summarized below:

The High Cost of Energy in Rural America (2018)[73]

This study examines the energy burden levels for households living in rural areas in the United States. Rural households have a higher median energy burden (4.4%) than

[73] Ross, L., Drehobl, A., and Stickles B. (July 2018). The High Cost of Energy in Rural America: Household Energy Burdens and Opportunities for Energy Efficiency. Retrieved from https://aceee.org/research-report/u1806

the national median energy burden (3.3%). Low-income households in rural areas spend the highest portion of their income on energy bills. In the Mid-Atlantic states, the median energy burden level for these households is 9.5%. Demographics also pay a factor in energy burden levels. Rural elderly households have a median energy burden 44% higher than non-elderly households; rural renters have a median energy burden 29% higher than owners; and non-white households have a median energy burden 19% higher than white households. Other factors, besides income level, may contribute to higher energy burden levels for rural households such as the condition of the home, a household's ability to invest in energy efficient equipment, and the availability of energy efficiency programs. Energy efficiency upgrades were found to reduce energy burden levels up to 25%. The study recommends, among other things, exploring low-risk or no-risk efficiency financing options, incorporating regional workshop development initiatives, and building relationships with area service providers to enhance program delivery.

Lifting the High Energy Burden in America's Largest Cities (2016)[74]

This study examined the energy burden levels of households living in 48 of the largest cities across the United States, including Philadelphia and Pittsburgh. The median energy burden for all households in this sample was 3.5%, but the median energy burden for low-income households was more than twice as high at 7.2%. The study promotes the use of weatherization programs to help improve housing stock for low-income households, noting that raising household efficiency to the median level could reduce the energy burden level by 35%. Benefits to energy efficiency programs include improved health and safety, reduced risk of rate increases, reduced costs associated with collections and shutoffs, and investment in the local economy. The study recommends that utilities track program participation by income level, renter versus owner, multifamily versus single family, and race/ethnicity to assess the impacts on different segments of the population. It also recommends regulators set goals and guidelines for energy savings, cost recovery, and cost-effectiveness testing.

PPL Electric Evaluation Report (2014) [75]

This study concluded that an energy conservation program, CARES, and a hardship fund can have a positive impact on reducing bills, increasing the ability to pay, and reducing arrearage.

Opinion Dynamics Low-Income Assistance Program Evaluation (2013)[76]

This study evaluated an anonymous utility's energy assistance program that provided reduced monthly payments and debt forgiveness to payment-troubled households based on family size, income, and electric use. The study noted that customers frequently left and re-entered the program (46% enrolled more than once). Participants who also received LIHEAP had a 14% lower average on-time payment rate than non-LIHEAP participants. Customers with lower PPAs had higher on-time payment rates, and more of these customers had on-time payment rates higher than the average. A sampling of customers found that 81% of the respondents reported taking action to try to reduce their energy usage after enrolling in the program; 70% reported that their electric usage either stayed the same or increased during this period.

UGI Gas and Penn Natural Gas Evaluation Report (2012) [77]

This study concludes that CAP participation has a large impact on energy affordability, decreasing energy burden, and improving payment behavior. On average, energy burdens among CAP participants declined from 15 to 10 percentage points. Compared to the pre-enrollment period, CAP customers were nearly twice as likely to pay their bills in full compared to their payment behavior prior to enrolling in CAP.

Home Energy Affordability in New York: The Affordability Gap (2011)[78]

This study defined an "affordable" energy burden as 6%, based on the theory that shelter costs should not exceed 30% of household income and that utility costs should not exceed 20% of shelter costs. 20% of 30% is 6%. Based on this measure, the study examined the energy affordability of New York households. Among other things, the study found demographic patterns correlated to energy affordability, including age, education, and gender. Elderly households were found to have smaller family sizes and less income; two-thirds of men and women living below the poverty level had only a high school diploma or less; and approximately 11% of men with full-time jobs live in poverty, compared to 6.5% of women.

Allegheny Power Universal Services Evaluation Report (2010) [79]

This study found that participation in CAP improved payment behavior; the average number of monthly payments per year increased from 8.6 to 9.4, while the coverage of the total bill – from cash and assistance payments - increased from 88% to 111%. While roughly 33% of participants paid their full bill in the prior year, 68% paid their full bill in the year after enrolling in CAP. Other positive results included a reduction in arrearage and the number of customers receiving termination notices; however, the actual termination rate did not change.

The Illinois PIPP Program Impact Evaluation (2009)[80]

This study found that enrollment in a PIP can increase the amount of energy used by households. Increased energy usage generally falls between 0.9% and 3.8%. However, data showed that a significant number of those households that increase their energy usage reported keeping their household temperature at unsafe heating levels prior to enrolling in a PIP. The study recommended coordinating PIP participants with weatherization and other energy conservation programs to offset any increases in energy usage.

LIHEAP Energy Burden Evaluation Study (2005)[81]

This study found that LIHEAP was effectively targeting the highest burden households (62% of LIHEAP recipients had high energy burdens) but that LIHEAP was not as successful in furnishing sufficient benefits to highly burdened and vulnerable households. The distinction was vulnerability. Vulnerable households are sensitive to the characteristics of household members, particularly households with at least one member aged 60 or over or with one or more members who are age 5 or younger. Under certain circumstances, non-low-income households can be vulnerable, and not all low-income households are vulnerable. This highlighted the need to consider other factors in addition to household income and to segment the eligible population to identify certain characteristics, such as the elderly. Geographic location, home ownership, and household size played important roles.

Measuring LIHEAP's Results: Responding to Home Energy Unaffordability (1999)[82]

This study tested empirically whether it would be accurate to equate "unaffordability" and "bill nonpayment" and concluded that the two are not the same. According to this study, paying utility bills in full and on time does not mean that these bills are affordable. Households may strive to make these utility payments and then struggle to afford other things such as food or medical care. The authors concluded that payment rates did not necessarily reflect the affordability of utility bills and recommended that "the concept of bill affordability should be replaced with a concept of bill sustainability" when evaluating the impact of energy assistance programs such as LIHEAP.

Determining the Cost-Effectiveness of Utility Late Payment Charges (1994)[83]

This study, which included analysis of households in Columbia Gas' Budget Plus Plan, determined that late charges for non-payment do not necessarily provide an incentive for more timely payments.

Observations

Pennsylvania's maximum energy burdens for CAPs, which range from 5% to 17% of household income, are much higher than neighboring states. Ohio has the second highest energy burden level for its utility payment assistance programs at 10% of household income. New York and New Jersey's utility payment assistance programs both have a maximum energy burden of 6%.

Pennsylvania households with incomes at or below 150% of the FPIG experience some of the highest energy burdens in the country. When counting the costs of all sources of energy, Pennsylvania residents with incomes at or below 50% of the FPIG had energy burden levels at 30% or higher for four of the five years of this study. Households that use electric non-heating may have higher energy burden levels than those reflected in this study if they use more expensive heating fuels, such as oil or propane.

A review of the other independent studies referenced above provides the following guidance:

---

[82] Fisher, Sheehan, & Colton. (May 1999). "Measuring LIHEAP's Results: Responding to Home Energy Unaffordability," *Public Finance and General Economics*. Retrieved from http://www.fsconline.com/downloads/Papers/1999%2005%20measure-liheap.pdf. Measuring LIHEAP's Results at i.

[83] Fisher, Sheehan, & Colton. (June 1994). "Determining the Cost-Effectiveness of Utility Late Payment Charges," *Public Finance and General Economics*. Retrieved from http://www.fsconline.com/downloads/Papers/1994%2007%20LATE-FEE.pdf. Determining the Cost-Effectiveness of Utility Late Payment Charges at 15.

- Although nearly eight-in-ten Pennsylvanians live in an urban area (78.7%),[84] households in rural areas may experience the highest energy burden levels due to poor housing stock in these areas. Focusing energy-efficiency education and weatherization services can help to reduce the energy burden disparity in these areas and help make CAPs more effective.

- Policymakers should not confuse unaffordability with non-payment behavior. Customers can make payments in full and on time, yet their bills may still not be affordable when other (possibly neglected) household expenses are taken into account.

- Not every household in poverty or with high energy burdens will automatically experience energy bill payment problems.

- Although LIHEAP does serve the lowest income households with the highest energy burden, the concept of vulnerability must also be considered. Some populations, such as the elderly and families with young children or members with certain medical conditions, are more vulnerable than others.

- Knowing the characteristics of the intended population enables prioritization according to need. Demographic patterns – including age, education, and gender – may correlate to energy affordability. Elderly households may be more vulnerable to high energy burdens because they are more likely to live in smaller family sizes and with limited and fixed income.

- Factors other than income and customer characteristics will play a role in determining the effectiveness of an assistance program. Program design is important, including the application process and leveraging of resources.

- The ability to coordinate multiple programs so that the strengths and goals of one can offset or compensate for weaknesses of another is crucial.

- Customers enrolled in CAPs with lower arrearages are more likely to successfully improve their payment behavior. Lower PPAs at the time of entry into a program result in a greater likelihood of making payments in full and on time. The average account balance can potentially predict the likelihood that program participants will be successful or unsuccessful.

- CAPs can reduce energy burdens and improve payment behavior. Customers in a CAP will be more likely to pay their bills in full or on time.

[84] Pennsylvania State Data Center, Penn State Harrisburg. (October 2012). Pennsylvania's Urban and Rural Population. Retrieved from http://pasdc.hbg.psu.edu/sdc/pasdc_files/researchbriefs/Urban_Rural_SF1_RB.pdf.

- Negative penalties such as late charges have little impact on encouraging more timely payment behavior.

X. CAP Costs and Forecasts

Objective

To identify the cost components of CAP and forecast the future costs of the program under current conditions and with adjustments to CAP enrollment numbers and energy burdens.

Background

The Univeral Service Reporting Requirements (USRR)[85] require the major gas and electric utilities to report data on the three components of CAP program costs: CAP administration and monitoring, CAP credits, and arrearage forgiveness.

Administrative costs include: contract and utility staffing, account monitoring, intake, outreach, consumer education and conservation training, recertification processing, computer programming, program evaluation, and other fixed overhead costs. Account monitoring costs include collection expenses, as well as other operation and maintenance expenses.

Of the three CAP cost components, CAP credits comprise the largest portion. CAP credits are the difference between the cost of utility service at tariff rates and price of utility service that CAP participants are asked to pay. Another key factor that drives the total cost of a CAP is the average CAP enrollment.

The cost of arrearage forgiveness is dependent on the PPAs of households when they enroll in CAPs and their adherence to CAP requirements. The more frequently the CAP customers pay their bills in full and on-time, the greater the amount of PPA forgiveness.

Methodology

To perform the analysis of total CAP costs, staff reviewed the total gross cost of all CAP components, average CAP enrollments, and the average number of residential customers for each of the EDC and NGDC utilities as reported in the *Universal Service Programs and Collection Performance Reports* (USRs) from 2012-2017.[86]

CAP budgets from approved or proposed utility USECPs were used to determine cost projections four years into the future, until 2021.[87] These projections are shown two

[85] 52 Pa. Code § 62.5 (2)(ii)(C)(III) for NGDCs and 52 Pa. Code § 54.75(2)(ii)(C)(III) for EDCs.
[86] http://www.puc.pa.gov/filing_resources/universal_service_reports.aspx
[87] Staff used projected CAP costs for 2018 to 2021 from the utilities' USECPs, rather than using regression to forecast CAP costs from the 2012-2016 data. Staff determined that the USECP

ways: (1) the total CAP costs from utility USECPs and (2) the impact of the CAP costs per non-CAP residential customer. Staff forecast the 2018-2021 average CAP enrollment and residential customer numbers. Staff then adjusted the costs to show a range of potential increases and decreases (+10%, +5%, +1%, -1%, -5%, -10%) to the 2018-2021 projected residential non-CAP costs.

Finally, staff created a model based on actual 2012-2016 CAP costs and energy burden levels. Staff was able to adjust the energy burden levels, holding the other variables static, and estimate the incremental CAP costs based on potential new percent-of-income energy burden levels. The model can be used to examine other potential percent-of-income energy burdens.

Data Limitations

The total CAP cost data and cost components were reviewed in aggregate for each utility, as the utilities do not report costs broken down by heating/non-heating or by poverty level as part of the USR.

Analysis

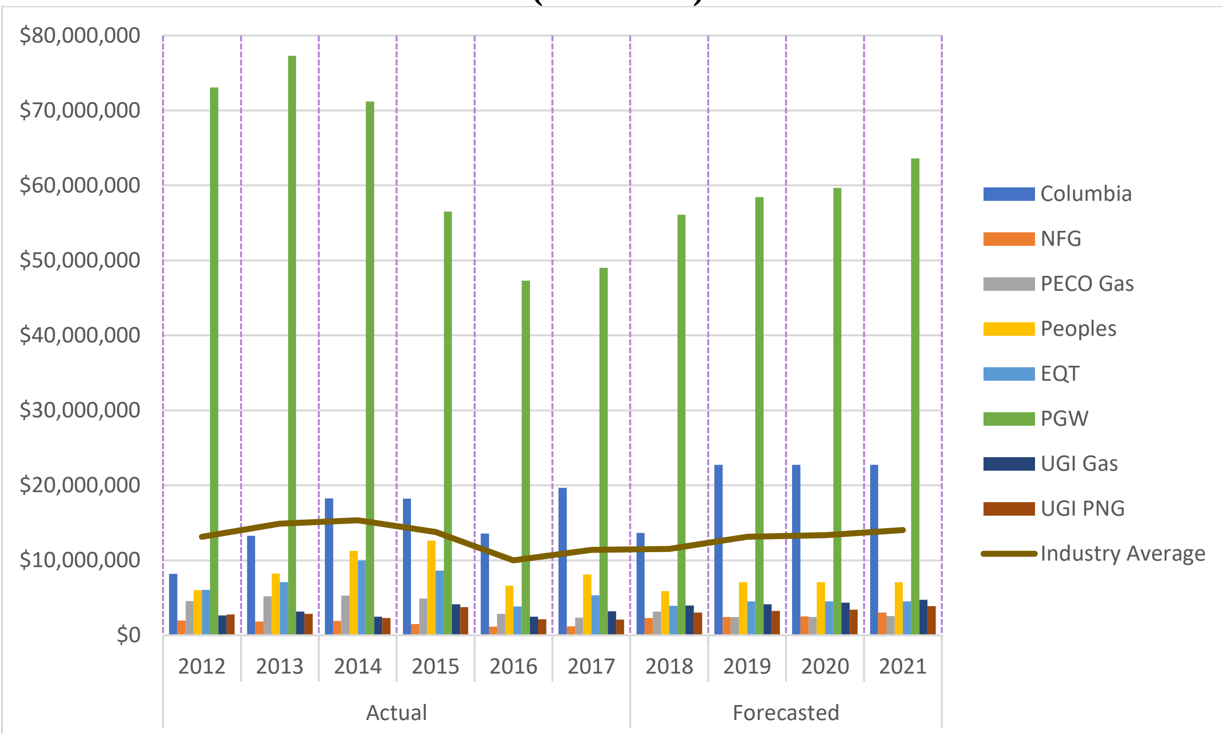
Staff analyzed the actual 2012-2017 costs of CAPs, number of residential customers, and average CAP enrollments from USR data in order to determine the costs of CAPs per non-CAP residential customer, calculated: CAP costs/(residential customers-average CAP enrollment). Staff used approved and proposed USECP CAP budgets for 2018-2021 and then forecast the 2018-2021 residential customer and average CAP enrollment levels using a regression analysis (when necessary).

Staff also created a separate model to estimate the impacts of adjusting the energy burden levels going forward.

CAP budgets were approximately 7% higher than actual CAP costs for 2015 through 2017. *See* Appendix 9.M.1: Variance between USECP CAP Cost Projections and Actual CAP Costs – Energy Industry as a Whole. Staff did not factor this variance into the model.

NGDC CAP Costs

Table 10-1
NGDC - CAP Totals With 4-Year Forecasting
(2018-2021)

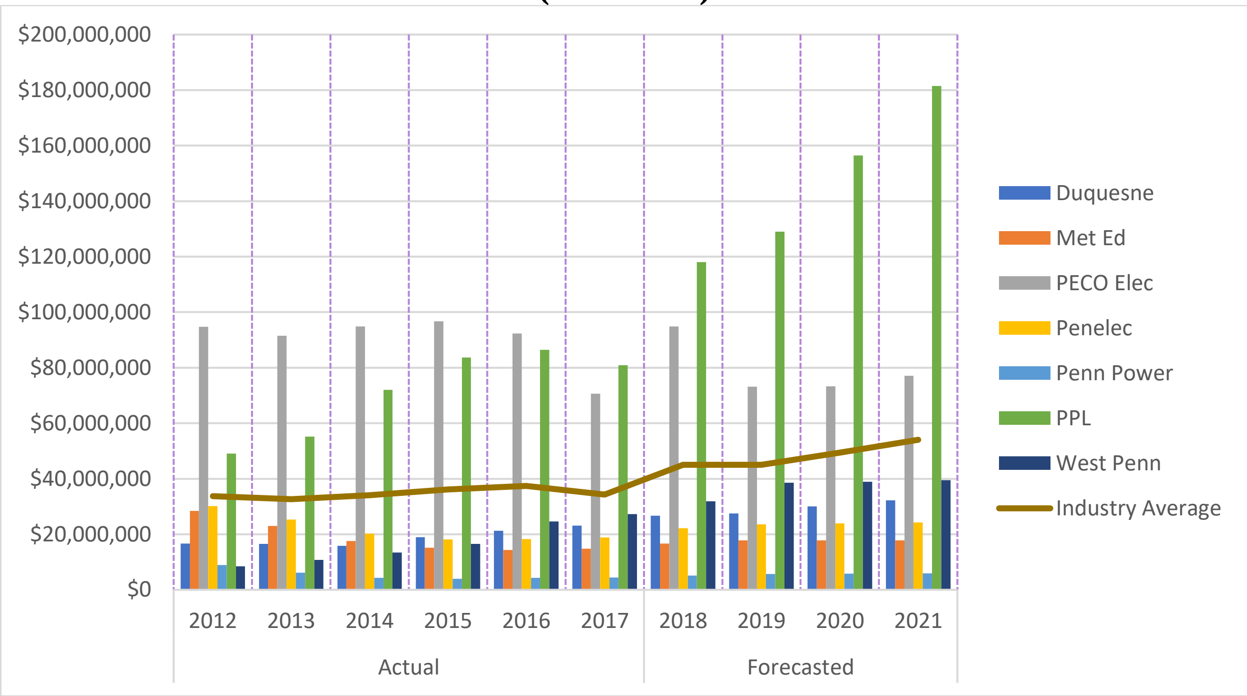


The historic CAP cost data show that PGW had the highest CAP costs of the NGDCs. PGW's CAP costs are recovered from rate classes other than just residential.[88] While CAP costs for PGW were still much higher than any other NGDC, they decreased from a peak of over $77.2 million in 2013 to $47.3 million in 2016. However, based on PGW's projected CAP budgets in its 2017-2020 USECP, PGW's CAP costs are anticipated to increase annually, growing to $63.6 million by 2021. Peoples' CAP costs have remained fairly steady since 2012 and are projected to remain fairly constant. Columbia Gas' CAP costs have risen from $8.1 million in 2012 and may reach a projected cost of over $22.7 million in 2021; Columbia Gas has the second highest NGDC CAP costs overall. NFG's CAP costs are forecast to increase from $1.2 million in 2017 to just over $3 million in 2021. The forecasting model projects the overall industry average for NGDC CAP costs will increase annually over the next four years, from $11.4 million in 2017 to over $14 million in 2021. *See* Table 10-1.

[88] PGW, as a city NGDC, is able to recover its CAP and other universal service program costs from the following classes, at different allocation percentages each year: residential, commercial, industrial, municipal service, and the Philadelphia Housing Authority (PHA).

EDC CAP Costs

Table 10-2
EDC - Total Gross CAP Totals With 4-Year Forecasting
(2018-2021)



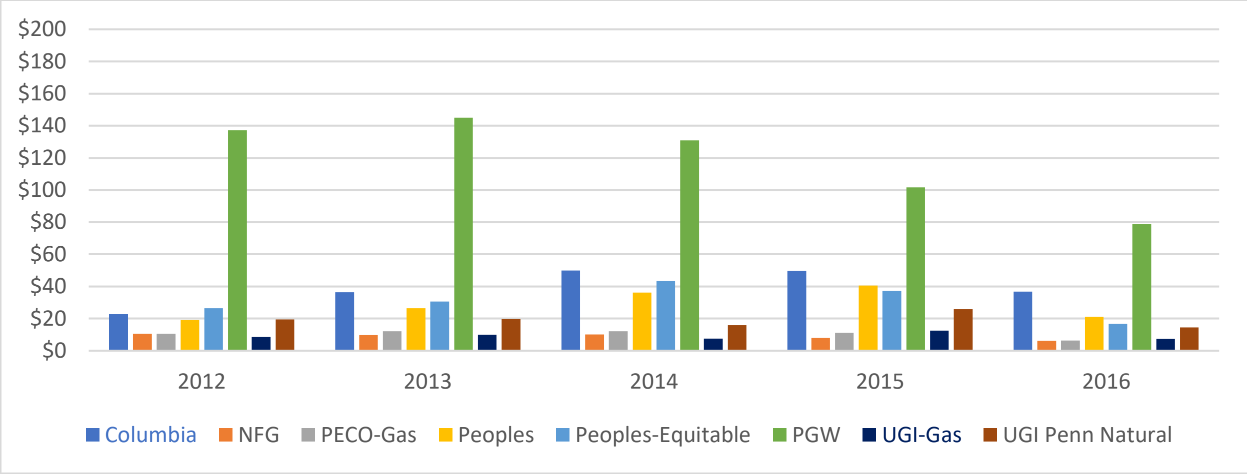
The historic CAP cost data show that PECO Electric and PPL had the highest CAP costs of the EDCs. PECO Electric's CAP costs remained fairly steady (between $92 to 96 million) from2012 through 2016. However, PECO Electric changed from a rate discount to a percent of income (PIP) CAP billing structure in October 2016, and this change is reflected in the lower projected CAP costs (between $73 to $77 million) through 2021. PPL's CAP costs have risen from $49.1 million in 2012 and may reach a projected cost of over $181.4 million in 2021. While PPL's 2020 and 2021 CAP costs are based on staff forecasting that does not take into account all possible factors, PPL's costs will likely continue to increase.

Forecasting shows the overall industry average for electric CAP costs will experience a sizeable increase over the next four years; from $34.3 million in 2017 to over $54 million by 2021. *See* Table 10-2.

Costs of CAP per Non-CAP Residential Customer

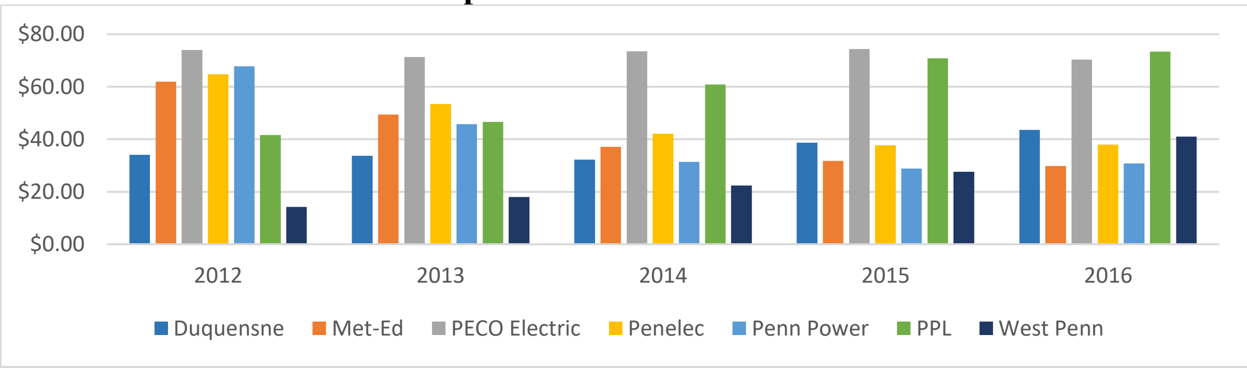
Another way to show the impact of CAP costs is to calculate costs per non-CAP residential customer. To do this, staff subtracted the average CAP enrollment from the number of residential customers to obtain the non-CAP residential customer totals. Staff then divided the total CAP cost by the average number of non-CAP residential customers for each utility: (*i.e.*, Total CAP Costs/Residential Customers-Average CAP Enrollment).

Table 10-3
Annual NGDC CAP Costs per Non-CAP Residential Customer 2012-2016



Based on historic data from 2012 to 2016, PGW had significantly higher costs per non-CAP residential customer than other NGDCs, even though PGW recovered its universal service program costs from other rate classes in addition to its residential class. The costs in the table above reflect only the historic residential portion of CAP costs for all utilities. *See* Table 10-3.

Table 10-4
Annual EDC CAP Costs per Non-CAP Residential Customer 2012-2016



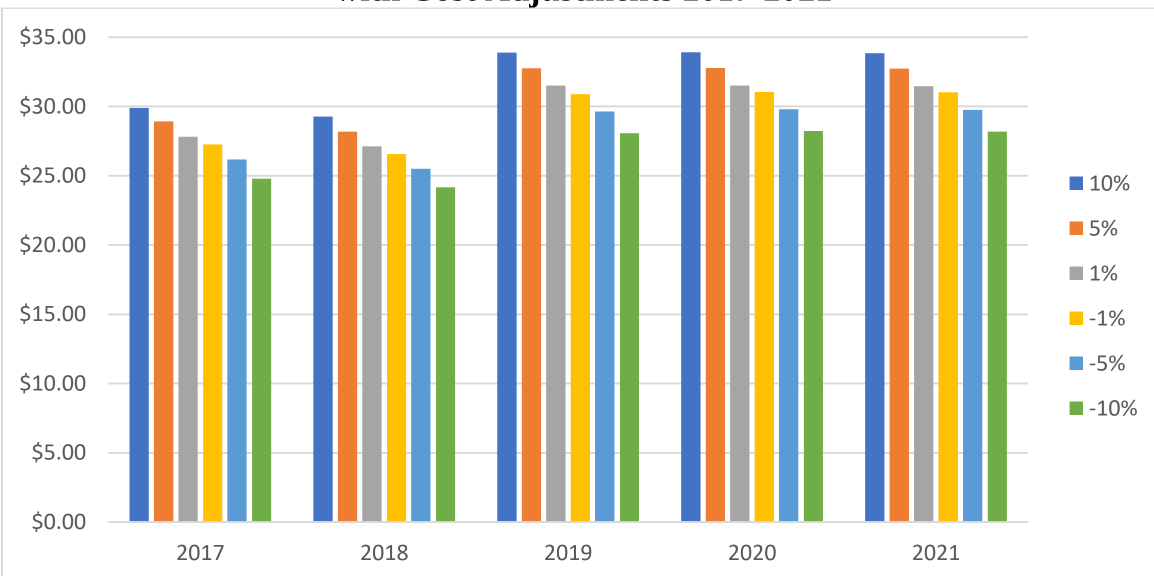
PECO Electric had the highest annual cost per non-CAP residential customer throughout the first four years of the study and was second highest in 2016. PPL's costs rose steadily and by the end of the study period were higher than PECO Electric's. Met-Ed's and Duquesne's annual CAP costs appear to have declined over the five-year period while West Penn's appear to have increased. *See* Table 10-4.

Projected Costs of CAPs Per Non-CAP Residential Customers with Cost Adjustments

Staff used projected CAP budgets from utility USECPs and regression analysis (for years in which no projected CAP budget was available) to forecast CAP costs for

2018 to 2021. Staff used the following adjustments to the costs per non-CAP residential customer: +10%, +5%, +1%, -1%, -5%, -10%. Due to the wide range in individual utility CAP costs, staff chose to perform this forecast at the EDC and NGDC industry level. The tables below show the energy industry CAP costs to non-CAP residential customers, as forecast for 2018 to 2021, but include the actual CAP costs for 2017, which were obtained from USR data. Staff has included the individual utility forecasts for non-CAP residential costs in the Appendix.[89]

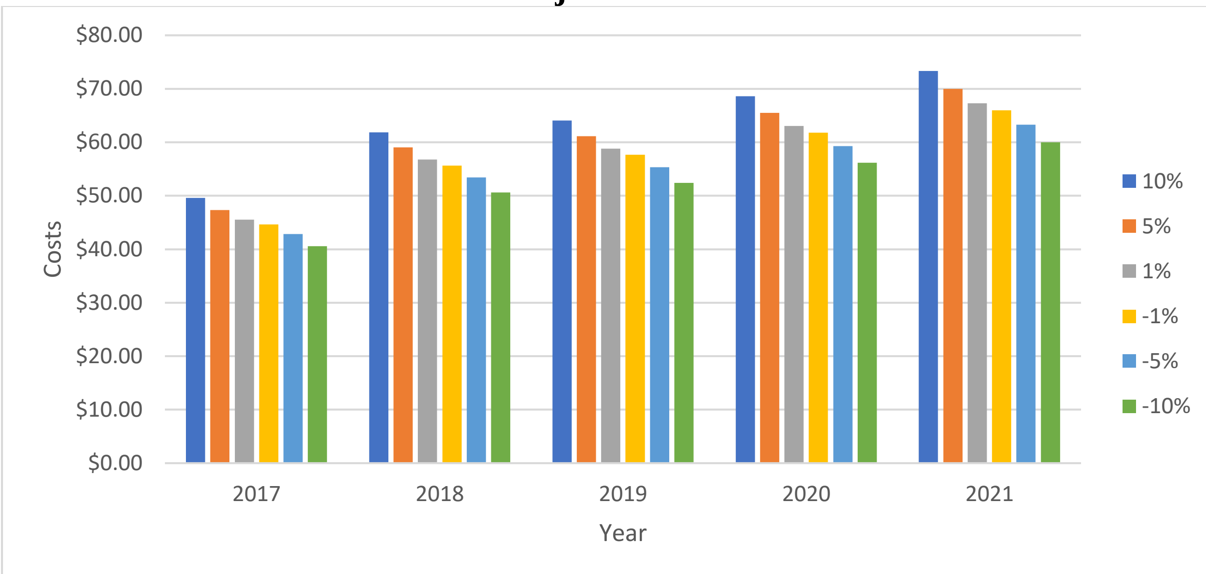
Table 10-5
NGDC Industry Predictions per Non-CAP Residential Customer with Cost Adjustments 2017-2021



By presenting the NGDC forecast at the industry level in Table 10-5 above, staff notes NGDC CAP costs per non-CAP residential customer will increase slightly by 2019, but otherwise remain relatively stable through 2021.

[89] See Appendices 9.D and 9.E.

Table 10-6
EDC Industry Predictions per Non-CAP Residential Customer with Cost Adjustments 2017-2021



By presenting the EDC forecast at the industry level in Table 10-6 above, staff notes an overall slightly increasing annual trend in the CAP costs per non-CAP residential customer. This increasing trend is consistent with the forecast trend noted above in the forecast for each individual EDC's CAP costs from 2018 to 2021.

Energy Burden Model

Staff developed a model that estimates the incremental costs to a CAP if energy burdens are adjusted. As noted earlier, most of Pennsylvania's neighboring states use lower maximum energy burdens. Ohio has a maximum energy burden of 10%, New York and New Jersey have maximums of 6%. For comparison purposes, staff projected the impact to Pennsylvania's CAP costs as if it adopted Ohio's 10% maximum energy burden based on the following levels: 10% for electric heating accounts, 4% for electric non-heating accounts, and 6% for gas heating accounts.

This model is based on the data collected from the utilities for this report from 2012 to 2016. The components used included the 2012 to 2016 calculated energy burdens by FPIG level for each utility, the 2012 to 2016 average annual CAP bill amounts, the 2012 to 2016 average annual CAP customer income, and the 2012 to 2016 average annual number of CAP accounts billed.

Staff did not incorporate any national energy prices[90] or usage forecasts into the model, as that data would be outdated by the time this report is released. Staff has,

[90] **Source:** U.S. Energy Information Administration (EIA)

however, included a summary table and links to the most recent NGDC and EDC forecasts, published in their respective reports on the PUC website.[91]

Additionally, staff's energy burden model does not take into consideration: (1) any possible reductions in CAP costs if some CAP customers are required to pay more at the selected energy burdens; (2) whether rate discount pricing might be better for some CAP customers; (3) CAP costs borne by PGW's non-residential ratepayers; (4) utility CAP credit limits; (5) system/administrative costs associated with adopting new energy burdens; and (6) factors specific to each utility.

The average energy burdens during the study period were calculated by dividing the average annual CAP bill by the average annual CAP income. New average annual CAP bills (by FPIG level), tied to a percent of income, were calculated using average annual CAP income.

Staff used Columbia Gas data to demonstrate this energy burden model. Dollar amounts and numbers may have been rounded to nearest whole amounts for the following example:

Step 1: Columbia Gas' Average Annual CAP Bill by FPIG Level

AVG 2012-2016		
50	100	150
$585.40	$694.00	$725.40

Step 2: Columbia Gas' Average Annual CAP Income by FPIG Level

AVG 2012-2016		
50	100	150
$5,582	$12,505	$22,354

Step 3: Columbia Gas' Calculated Average Energy Burden by FPIG Level

AVG 2012-2016		
50	100	150
10.49	5.55	3.24

https://www.eia.gov/outlooks/aeo/data/browser/#/?id=3-AEO2018&region=1-0&cases=ref2018&start=2016&end=2030&f=A&linechart=&map=ref2018-d121317a.4-3-AEO2018.1-0&ctype=linechart&sourcekey=0
[91] *See* Appendix 9.L.

Step 4: Columbia Gas' Estimated Average Annual CAP Bill at 6% by FPIG Level

AVG 2012-2016		
50	100	150
$334.93	$750.29	$1,341.26

The model compares the resulting estimated average CAP bill amounts to the corresponding actual annual average CAP bill amounts, by FPIG level, for 2012 to 2016. Some FPIG levels showed the difference as a negative number – which represents the amount of discount/CAP Credit/LIHEAP that would be needed to ***decrease*** the average annual CAP bill to the new estimated average CAP bill amount. Some FPIG levels show the difference as a positive number – which means that the average CAP bill is already below the selected energy burdens. This would not add directly to the CAP costs in this model, as CAP customers would have to pay the incremental increases in the bill. Staff set the estimated average CAP bills for those FPIG levels to $0 in the model and then calculated the change needed to obtain the average cost of change for each FPIG level.

Step 5: Columbia Gas' Change Needed to Reach 6% CAP Bill by FPIG Level

Columbia Gas	AVG 2012-2016		
	50	100	150
Estimated 6% CAP Bill	$334.93	$750.29	$1,341.26
Average CAP Bill	$585.40	$694.00	$725.40
Change to Reach 6%	-$250.47	$0.00	$0.00

Staff then multiplied the average estimated change in CAP billing by the average number of CAP accounts billed from 2012 to 2016 for each FPIG level.

Step 6: Columbia Gas' Incremental CAP Cost for Customers in < 50% FPIG

50		50		50
-$250.47	X	4558.15	=	-$1,141,680

The resulting dollar amounts represent the incremental cost that would be necessary to bring the average CAP bills in each FPIG level to the selected energy burdens. The dollar amounts are presented in the graphs below by individual utility and are expressed as negative numbers because they represent the additional discount (*i.e.*, CAP credits). The customers in the FPIG levels that were currently under the selected energy burdens are represented with $0 and may see an increase in average CAP bills.

The cost projections presented in the following graphs do not take into account any administrative or programming costs that the utilities would incur to transition the CAP customers to new energy burdens. In addition, these estimated costs do not consider any limits placed on CAP credits by individual utilities. The model does not consider the possibility of a reduction in CAP credits resulting from increased payments from those

CAP customers who currently have less than a 10% energy burden. Further, this model does not consider rate discount pricing. The estimates in this model are not meant to be inclusive of all costs or factors but are provided to give an approximation of costs and are based on the data reported by the utilities for this study.

Table 10-7
NGDC CAP Heating – Discount Needed To Reach 6% Energy Burden

	Columbia	PECO Gas	Peoples	EQT	PGW	UGI Gas	UGI PNG
Poverty Level 0-50%	-$1,141,671	-$949,472	-$482,898	-$644,602	-$1,070,907	-$495,780	-$340,481
Poverty Level 51-100%	$0	-$1,455,171	-$988,893	-$1,571,350	-$12,030,42	-$473,414	-$576,603
Poverty Level 101-150%	$0	-$1,071,488	$0	-$338,627	-$7,526,891	-$156,751	-$191,032

Columbia Gas would only incur costs in this model for customers at the 0 to 50% FPIG level. Peoples Gas would incur costs from the 0 to 50% and 51 to 100% FPIG levels but not from the 101 to 150% FPIG level. PGW would incur the costliest transition, particularly in the 51 to 100% FPIG level. *See* Table 10-7.

Table 10-8
EDC CAP Electric Heating – Additional Discount Needed for 10% Energy Burden

	Duquesne	Met Ed	PECO Electric	Penelec	Penn Power	PPL	West Penn
Poverty Level 0-50%	-$508,936	-$94,059	-$2,704,923	-$145,120	-$173,337	-$931,182	-$617,331
Poverty Level 51-100%	-$314,354	$0	-$3,027,842	$0	-$17,530	$0	-$60,351
Poverty Level 101-150%	$0	$0	-$680,776	$0	$0	$0	$0

All EDCs would incur costs at the 0 to 50% FPIG level to bring all of the CAP electric heating customers to a 10% energy burden. PECO Electric and PPL would incur the largest overall costs to align all heating customers to a 10% energy burden. However, all the EDCs except for PECO Electric would have no incremental change of costs in the 101 to 150% FPIG level. *See* Table 10-8.

Table 10-9
EDC CAP Electric Non-Heat – Discount Needed To Reach 4% Energy Burden

	Duquesne	Met Ed	PECO Electric	Penelec	Penn Power	PPL	West Penn
Poverty Level 0-50%	-$4,912,741	-$952,977	-$10,837,68	-$1,381,508	-$542,033	-$2,676,214	-$1,979,613
Poverty Level 51-100%	-$6,543,038	-$414,068	-$15,107,48	$0	-$187,418	-$4,442,829	-$2,430,374
Poverty Level 101-150%	-$1,872,303	$0	-$5,708,105	$0	-$108,075	-$402,887	-$1,158,215

The CAP electric non-heating customers make up the costliest of the account types to transition to a lower energy burden. Currently, the majority of EDC non-heating CAP customers have energy burdens that would exceed 4%. Penelec would have the fewest CAP customers to transition and would only incur increased costs from the 0 to 50% FPIG level. *See* Table 10-9.

Table 10-10
Estimated Total Cost to Change All FPIG Levels of CAP Gas Heating Customers to Energy Burdens of 6%

	Columbia	PECO Gas	Peoples	EQT	PGW	UGI Gas	UGI PNG
Amount	-$1,141,671	-$3,476,132	-$1,471,791	-$2,554,578	-$20,628,225	-$1,125,945	-$1,108,115

Table 10-11
Estimated Total Cost to Change All FPIG Levels of CAP Electric Heating Customers to Energy Burdens of 10%

	Duquesne	Met Ed	PECO Electric	Penelec	Penn Power	PPL	West Penn
Amount	-$823,290	-$94,059	-$6,413,541	-$145,120	-$190,867	-$931,182	-$677,682

Table 10-12
Estimated Total Cost to Change All FPIG Levels of CAP Electric Non-Heating Customers to Energy Burdens of 4%

	Duquesne	Met Ed	PECO Electric	Penelec	Penn Power	PPL	West Penn
Amount	-$13,328,083	-$1,367,045	-$31,653,275	-$1,381,508	-$837,526	-$7,521,930	-$5,568,203

The total costs for each utility within the respective CAP segment are illustrated in the previous tables presented in Tables 10-10 to 10-12.

Most NGDCs would see CAP cost increases of approximately $1 million. PGW's CAP budget, however, would increase by approximately $21 million. The EDCs would have more overall costs because of the need to transition both heating and non-heating CAP customers from current energy burdens to new lower energy burdens. *See* Table 10-10

Most EDCs would see CAP cost increases of less than $9 million. Met-Ed, Penn Power, and Penelec CAP costs would increase between $1 to 2 million. PECO Electric would experience a $38 million increase to its CAP costs. *See* Table 10-11 and 10-12.

The total cost to change all CAP customers in each segment represented in Tables 10-10 to 10-12 are summarized in Table 10-13 below.

Table 10-13
Incremental Cost to Change Current CAP Customers in Each Segment with Energy Burdens Higher than 10%, 6%, 4%, to the Targeted Energy Burdens Levels

CAP Customer Segment	Segment Cost	Incremental Additional Cost per Non-CAP Residential Customer	2012-2016	
			Average Number Residential Customers	Average CAP Enrollment
EDC Heating Segment (10%)	$9,275,741	$2.00	4,938,754	293,023
EDC Non-Heating Segment (4%)	$61,657,570	$13.27		
EDC Total		$15.27		
Gas Heating Segment (6%)	$31,506,457	$13.08	2,574,806	165,392
Total for EDC and NGDC Segments (10%, 4%, 6%)	$102,439,768		7,513,560	458,415
Weighted Average of Annual Cost Impact to Each EDC and NGDC Residential Non-CAP Customer		$14.52		

The incremental cost to non-CAP residential customers is calculated by first subtracting the average CAP enrollment from the average number of residential customers to get the non-CAP customer number. Then, the segment cost is divided by the non-CAP residential customer number to produce an incremental cost for each segment. The weighted cost represents the incremental cost across all EDC and NGDC non-CAP residential customers.

The additional CAP discounts, based on the 2012 to 2016 data used in the staff model, would have resulted in a weighted average annual increase of $14.52 to non-CAP residential ratepayer energy bills for the utilities in this study based on average customer counts from 2012 through 2016.[92]

Observations

Depending on the utility, NGDC non-CAP residential customers have paid between $10 and $145 annually to cover CAP costs over the study period. This does not factor in how much PGW commercial and industrial customers paid to cover CAP costs.

Depending on the utility, EDC non-CAP residential customers have paid between $15 and nearly $80 annually to cover CAP costs over the study period.

Despite an industry drop in CAP expenditures from 2012-2016, NDGC and EDC CAP costs are projected to increase annually through 2021.

---

[92] The results of this model are not projections of future CAP costs at a maximum energy burden of 10%. To use this model to forecast future CAP costs at various energy burden maximums would require additional data from the utilities.

The overall average costs per non-CAP residential customer are also anticipated to increase through 2021, varying by CAP enrollments levels. EDC customers will experience the biggest increase, with average annual CAP costs recovered from non-CAP residential customers increasing by approximately $20 from 2017 to 2021.

Based on average CAP bill and income levels, the total amount of additional discounts (*i.e.*, CAP credits) needed to establish maximum energy burdens of 6% for gas heating, 4% for electric non-heating, and 10% for electric heating would be approximately $102 million. This amount breaks down to approximately $32 million for gas heating, $62 million for electric non-heating, and $9 million for electric heating. This additional CAP cost would increase gas and electric bills for non-CAP residential ratepayers by approximately $15 as a statewide average for customers of the larger energy utilities.

The energy burden model, developed by staff, used in this study does not take into consideration: (1) any possible reductions in CAP costs if some CAP customers are required to pay more at the selected energy burdens; (2) whether rate discount pricing might be better for some CAP customers; (3) CAP costs borne by PGW's non-residential ratepayers; (4) utility CAP credit limits; (5) system/administrative costs associated with adopting new energy burdens; and (6) factors specific to each utility.

XI. Conclusion

The Commission initiated a study of energy affordability for low-income customers in Pennsylvania in its Order at Docket No. M-2017-2587711 entered on May 5, 2017. This staff report, notice of which will be published in the *Pennsylvania Bulletin* with provisions for comment and reply comment periods as necessary, will be published to the Commission's website. This report is a staff work product and is not binding on the Commission. Nor is this staff report indicative of how the Commission may decide to act on universal service matters in this or other dockets. 52 Pa. Code § 1.96. The legal, policy, and procedural issues regarding energy burdens remain under Commission review and may be factored into a subsequent order at this or other dockets.

This study serves as a starting point for the Commission's review of energy burdens.[93] It provides insight into the effectiveness of CAPs in serving Pennsylvania's low-income population. Although this study does not identify an "affordable" energy burden level for customers enrolled in customer assistance programs, it attempts to measure whether the various CAP payment designs met universal service goals such as reducing debt, improving customer payment habits, reducing defaults and terminations, and reducing the number of customers in debt who are not on payment agreements.

Staff identified inconsistencies and limitations in the reported data that impacted the analysis. Reasons for data variations included policy and procedure changes implemented by the utilities during the five-year time frame, specific enhancements to their systems, changes to their low-income programs, and mergers/acquisitions. Staff also found many utilities interpreted, tracked, and reported information differently.

The report notes a wide disparity in the average percent of household income spent on natural gas and electric services by non-CAP residential and CAP customers. Non-CAP residential accounts had an average energy burden of 4% for gas heating and electric non-heating or 4% for electric heating. In comparison, CAP customers with gas heating and electric non-heating had a combined average energy burden of 12% to 14%,[94] and CAP customers with electric heat have an average energy burden of 8 to 10%.

Many CAP customers with incomes in the 0% to 50% FPIG level were billed, on average, at energy burdens higher than the maximum ranges in the CAP Policy Statement. This pattern was not as apparent for CAP customers at the higher FPIG levels.

[93] In regard to energy burdens for all low-income customers, the utilities that were queried for this study were unable to identify or provide income information on low-income households that did not participate in their CAPs or other universal service programs.
[94] The average energy burden was 7 to 8% for NGDC CAP heating customers and 5 to 6% for EDC non-heating CAP customers.

Despite the LIHEAP impacts on energy burdens for CAP customers across all FPIG levels and energy types, average CAP households at 0 to 50% FPIG level had average energy burdens that exceeded the CAP Policy Statement guidelines.

Utilities with CAP enrollment restrictions beyond income-qualifications reported higher PPA balances. EDCs reported *fewer* CAP heating customers at the 101 to 150% FPIG level paid their bills in comparison to the percentage of bills paid by customers at the 51 to 100% FPIG level.

There was little consistency in the way the utilities report, track, and respond to CAP defaults. Further, utilities varied in how they tracked and reported CAP terminations.

The number of CLI customers in debt and not on a payment agreement generally decreased across utilities during this study period, which suggests that CLI customers were enrolling in CAPs or payment agreements and were thus less vulnerable to service termination.

Despite an industry drop in CAP expenditures from 2012-2016, NDGC and EDC CAP costs are projected to increase annually through 2021. The overall average costs per non-CAP residential customer are also anticipated to increase through 2021, varying by CAP enrollments levels. EDC customers will experience the biggest increase, with average annual CAP costs recovered from non-CAP residential customers increasing by approximately $20 from 2017 to 2021.

Historically, non-CAP residential customers have paid on average between approximately $10/year and $145/year to cover CAP costs over the study period. CAP costs borne by PGW non-residential customers have not been factored in.

Pennsylvania's maximum energy burdens in the CAP Policy Statement are higher than maximum energy burdens used by neighboring states. Ohio – a state with similar climate, energy use, and demographics – has a maximum energy burden of 10% for its payment assistance program. Based on a model developed by staff, adopting a 10% maximum energy burden[95] across all FPIG levels in Pennsylvania would increase CAP discounts (*i.e.*, the costs borne by non-CAP residential customers) by approximately $102 million per year. This staff forecast, however, does not factor in all the impacts associated with an energy burden change (*e.g.*, costs of implementing a system change, whether rate discount pricing might be better for some CAP customers, etc.). Further, the staff forecast does not consider the possibility of a reduction in CAP credits resulting from increased payments from those CAP customers who currently have less than a 10% energy burden.

Staff further notes that, in addition to changes implemented during the study time frame, utilities have also implemented changes in their CAPs and other universal service

[95] Specifically, 10% for electric heating, 6% for gas heating, and 4% for electric non-heating.

programs since 2016. Such changes are on-going and may have an impact on the observations drawn by this study. Inspection of future data may substantiate trends as well as identify the aspects of CAPs that appear to work well or that produce better customer outcomes. Collection of valid data that can be compared across income levels, within industry groups, and between industry groups would increase the reliability of projections and better evaluate the success of CAPs.

The appendices that follow provide more details on the data, third-party articles, staff models, and demographics referenced in this staff report.

XII. Appendices

Table of Appendices

Appendix 1 – NGDC and EDC Demographic Profiles

Appendix 1.A: NGDC Service Territory Demographic Profiles

This Appendix provides a demographic profile of each EDC and NGDC service territory. In many cases, the jurisdictional boundary of a utility's service territory does not match municipal and county boundaries. The demographic data is not based on utility service area boundaries

Staff worked with Pennsylvania Spatial Data Access (PASDA) to create a census-based profile for each utility, based on a service area Geographic Information System (GIS) layer provided to the Commission by the utilities. PASDA utilized the GIS service area layers along with data from the Environmental Systems Research Institute (Esri) and the American Community Survey (ACS). The demographic data provided for each utility is data from the latest ACS survey (2012-2016) unless otherwise noted. The ACS demographic data is presented by households and/or population.[96]

Each service area profile is specific to the utility, although staff recognizes that the utility service areas overlap and, therefore, some demographic data will be counted in multiple service areas. This section also includes data about median and *per capita* incomes.[97]

---

[96] As defined by ACS, a household is composed of one or more people who occupy a housing unit. See https://www.census.gov/programs-surveys/acs/technical-documentation/code-lists.html. Population is defined as the whole number of inhabitants of a particular town, area, or country.
[97] "*Per capita* income" is defined as the average income earned by each person in a given area. Example, two income earners in the same household would be counted separately when measuring *per capita* income.

*No data available for the year.

**Median Annual Income for Residential cases is from the ESRI (Environmental Systems Research Institute) system and does not distinguish between heat and non-heat accounts and is an average from 2012-2016. Since the Number of Bills Issued and Billings are available for heating and non-heating accounts for all of the years, the total Median Annual Income is used as the base for calculating Energy Burden by heating status and year.

Appendix 2.B: CAP Industry Average NGDC and EDC Energy Burdens

Appendix 3 – Impact of LIHEAP Grants on Energy Burden Levels

Appendix 3.A: Tables 4-1 to 4-9 Impact of LIHEAP Grants on Energy Burdens for CAP Customers

The impact of LIHEAP on energy burdens is shown for gas and electric heating and non-heating LIHEAP recipients for all FPIG levels using the average dollar amount of LIHEAP grants applied and the average CAP bill. The utilities that did not provide all three of the data points (LIHEAP Recipient CAP Bill, LIHEAP Dollars and LIHEAP Recipient CAP Income) necessary for this analysis by heat type or poverty level are excluded. Some utilities provided estimates for some data points.

Appendix 8 – State Survey Responses

Staff received eight responses to the survey. None of the responders provided data for every question.[98] These summaries have been supplemented by limited staff research.

Question 1: Excluding LIHEAP, what utility and/or energy assistance programs does your state offer to low-income customers?

<u>Colorado:</u>

Energy Outreach Colorado
- Low-income assistance
- Program specifically targeted to low-income customers for each utility
- Paid by rate charged to each residential non-participant monthly bill

<u>Michigan:</u>

Michigan Energy Assistance Program
- Implemented by utilities
- Funded by state's Low-Income Energy Assistance Fund
- Utilities can opt in or out on an annual basis

<u>Indiana:</u>

A state-funded energy assistance program which provides benefits to homeowners only.[99]

<u>District of Columbia:</u>

Residential Aid Discount Program
- Offered by Pepco for electric customers. This program offers a credit that covers full customer charges for energy distribution and exemption for several surcharges. The combined discount equals about 30% of the typical bill for eligible customers.

Residential Essential Service Program (RES)
- Offered for gas customers of Washington Gas. The program offers a discount to eligible Pepco residential customers in D.C. The discount is a percentage reduction in the distribution portion of the customer's bill

[98] The actual survey questions and responses have been summarized in this Appendix.
[99] Staff notes that additional information about Indiana's program is available at: https://www.in.gov/ihcda/2329.htm.

for the winter months, November through April, resulting in approximately 25% reduction in charges. RES also provides for an automatic short-term increase in this reduction if gas prices increase above a specific historical average.

Ohio:

PIPP Plus

- Customers are eligible if their household income is at or below 150% of the FPIG level. (Ohio LIHEAP income eligibility guidelines are set at or below 175% of the FPIG level.)

Winter Reconnect Orders

- Issued annually by the Public Utility Commission of Ohio, allowing customers who are disconnected or being threatened with disconnection to pay a maximum of $175 to maintain or restore their utility service once per winter heating season.

The electric and gas companies offer their own specific programs to assist eligible customers with paying their utility bills.

Question 2: Does your state have a definition for an "affordable" energy burden?

No respondents reported a definition for an affordable energy burden.

Question 3: Please provide an explanation of how your state calculates a household's energy burden (i.e., statewide; includes housing expenses) and if there is a difference based on fuel type (i.e., electric or gas; heating/non-heating account).

Colorado:

Eligible participants are limited to those with a household income at or below 186% of the current federal poverty level, or, if the utility applies Low-Income Energy Assistance Program (LEAP) benefits to offset the costs of the unaffordable portion of the participating customer's utility bill, the percent of the current federal poverty level set by the Colorado Department of Human Services, Division of Low-Income Energy Assistance for eligibility in the LEAP program.

Participant payments for natural gas bills rendered to participants shall not exceed an "affordable PIPP." For accounts for which natural gas is the primary heating fuel, participant payments shall be no lower than 2% and not greater than 3% of the participant's household income.

Participant payments for electric bills rendered to participants shall not exceed an "affordable PIPP." The percentage of a participant's household income for which the participant is responsible shall be determined as follows:

A. For electric accounts for which electricity is the primary heating fuel, participant payments shall be no lower than 3% and not greater than 6% of the participant's household income; and

B. For electric accounts for which electricity is not the primary heating fuel, participant payments shall be no lower than 2% and not greater than 3% of the participant's household income.

Colorado does not perform any calculations. Each utility is required to calculate the total bill and the "affordable" portion of the average bill for each eligible participant. There is a small difference in the calculation for gas versus gas/electric.

Indiana:

Indiana does not calculate energy burden except for its Performance Measure Reporting. This is simply the total cost of energy compared to income.

Ohio:

Ohio does not calculate a household's energy burden. Electric and natural gas customers who qualify pay $10 or 6% of their gross monthly household income, whichever is greater, to the utility each month. If the utility provides both gas and electric services or if the customer has an all-electric home, the payment is $10 or 10% of the gross monthly income, whichever is greater. (*See* https://www.puco.ohio.gov/be-informed/consumer-topics/energy-assistance-programs-help-with-paying-your-utility-bills/) The eligibility threshold for LIHEAP is 60% of the State Median Income which is roughly 175% of the FPIG.

Question 4: Do you establish a target energy burden level for your utility and/or energy assistance programs?

Colorado and New Hampshire establish target energy burdens.
Colorado includes LIHEAP payments in the calculation for target energy burden levels.

Question5: Does your state use the same target energy burden for all programs, or are there different levels for each program or fuel type?

New Hampshire:

New Hampshire does not use energy burden as described above. The discount levels are set to bring the amount that the average participating customer pays between 4% and 5% of the average income for that discount tier. There are five discount tiers with discounts ranging from 8% to 76%.

Colorado:

In Colorado, a participant's minimum payment for an electric heating account shall be no more than $20 per month, and the minimum payment for a non-heating electric account shall be no more than $10 per month. For gas heating customers, with a household income of zero dollars, a utility may establish a minimum monthly payment amount of $10 per month or less.

Question 6: Does your state provide a CAP program? If yes, please describe program.

South Dakota does not offer CAPs.

New Hampshire

New Hampshire has CAPs but provided no additional information. Staff notes that additional information may be found at:
https://www.puc.nh.gov/consumer/electricassistanceprogram.htm

District of Columbia:

For electric, D.C. has the Residential Aid Discount (RAD) Program offered by Pepco. The credit covers the following charges: the full customer charge and energy charge for distribution and exemption from the following surcharges: the RAD Surcharge, the Sustainable Energy Trust Fund, and the Energy Assistance Trust Fund. Credits for these charges are individually listed on the customer's bills as "Residential Aid Credit (RAC) – Distribution" and "RAC Surcharges." Customers will receive the RAC whether or not they have a retail supplier. The full RAC is equal to approximately 30% of a typical RAD customer's bill. In addition, the D.C. Commission is working with stakeholders to develop an arrearage management plan.

For gas, D.C. has the Residential Essential Service (RES) offered by Washington Gas. The program offers eligible Pepco D.C. residential customers a discount on the distribution portion of the customer's bill from November through April. The discount is achieved through a percentage reduction of the distribution portion of a customer's bill, resulting in an approximately 25% reduction in the total bill. The RES additionally provides for an automatic short-term increase in the reduction to the distribution portion of the bill when purchased gas prices rise above a specified historic percentage. RES customer bills also indicate the costs of surcharges that RES customers are exempt from paying, specifically: RES surcharge; Sustainable Energy Trust Fund surcharge, and Energy Assistance Trust Fund surcharge. Customers can enroll in the RES program year-round; the enrollment year begins on October 1.

<u>Ohio:</u>

Ohio provided detailed information on three variations of its PIPP programs.

PIPP Plus is an extended payment arrangement that requires regulated gas and electric companies to accept payments based on a percentage of the household income for those customers who are at or below 150% of FPIG. The PIPP Plus payment amount is based on the household's countable income received during the previous 30 days. If a gas customer qualifies for PIPP Plus, he or she would pay 6% of the household's current gross monthly income to the gas company or a minimum of $10, whichever is greater, year-round. If electricity is not the primary heat source, a customer pays 6% of the household's current gross monthly income or a minimum of $10, whichever is greater, year-round. The customer of an all-electric household pays 10% of the household's monthly income or a minimum of $10, whichever is greater, year-round.

Graduate PIPP Plus allows customers who are no longer eligible to participate in PIPP Plus as a result of an increase in the household income or a change in the household size to continue to receive a reduction in their outstanding arrearages in return for making timely payments. Graduate PIPP Plus customers receive arrearage reduction for on-time and in-full payments. Customer will earn 1/12th credit on arrearages. Graduate PIPP Plus customer bills will be adjusted for the difference between the required installment payment and the current month's utility charges.

Post PIPP Plus is a 12-month payment plan for former PIPP Plus or former Graduate PIPP Plus customers who are no longer customers of the utility but still have an arrearage. Post PIPP Plus is only available in the 12 months immediately after a PIPP Plus account is closed. The customer enters into a payment plan to pay at least 1/60th of the final account arrears for 12 months. For each payment made, the utility will credit 1/12th of the customer's arrears. *See* https://development.ohio.gov/is/is_PIPP_plus_review.htm

Colorado:

Debt forgiveness is included in Colorado's authorized low-income assistance program.

Utility A: Customers must pay down the PPA to $300 before being allowed to enroll in the program and receive 1/24th PPA forgiveness per month over 24 months.

Utility B: PPAs of $500 or less are "retired" over 12 months; larger PPAs are retired over 24 months. This utility also offers a one-time forgiveness of up to $200.

Other utilities offer credit designed to reduce PPAs to zero over 12 months.

Regarding rate assistance, one utility offers a fixed monthly credit to customers who are LIHEAP recipients with income below 150% of the FPIG level and who agree to participate in a weatherization program and enroll in a budget billing plan.

Some utilities offer percentage of income plans for customers who receive LIHEAP and have incomes at or below 150% of the FPIG level, based on a utility formula.

For another utility, households at or below 100% of the FPIG level can receive a 25% discount based on their prior 12 months of usage, while customers between 100 and 150% of the FPIG level receive a 20% discount.

A gas utility offers customers who are LIHEAP recipients with household income at or below 125% of the FPIG level a tiered-maximum payment option:

- 2% of income if household income is at or below 75% of the FPIG level

- 2.5% of income if income is between 76 and 125% of the FPIG level

- 3% of income for households with incomes between 126 and 185% of the FPIG level

Question 7: If the state has a CAP program, what are the eligibility requirements?

New Hampshire:

For New Hampshire's Energy Assistance Program (EAP), the eligibility level is at or below 200% of the FPIG. For the gas discount program, it is categorical eligibility, with participation in one of 13 programs qualifying a customer.

District of Columbia:

Household Size	FY 2018 Maximum Annual Income
1	$30,142
2	$39,416
3	$48,691
4	$57,965
5	$67,239
6	$76,514
7	$78,253
8	$79,992

Ohio:

PIPP Plus eligibility - The customer must be at or below 150% of the FPIG and have an active account with a regulated utility.

Graduate PIPP Plus eligibility - The customer may elect to enroll on graduate PIPP Plus, or the customer must be income-ineligible for PIPP Plus. The customer must be current with all PIPP Plus payments.

Post PIPP eligibility - Plus-PIPP Plus or Graduate PIPP customers who contact the utility to close their account for the following reason(s):

a. Moving beyond the utility companies service territory.
b. Transferring to a residence where utility service is not in the former PIPP Plus or Graduate PIPP Plus customer's name.
c. Moving to a master-metered residence.

Question 8: How is your CAP program funded (i.e., through LIHEAP, residential rates, commercial rates, industrial rates, etc.)?

New Hampshire:

The EAP is funded through a per kWh system benefits charge on all electric bills, both residential and commercial. The gas low-income program is funded through a component of the local distribution adjustment clause (LDAC) assessed to all customer classes.

Ohio:

PIPP Plus is funded through all ratepayers based on kWh or Mcf.

Question 9: What is the total CAP program cost for your state for 2012-2016?

New Hampshire:

Year	CAP Cost
2012	$16,227,754 (10/1/2012 through 9/30/2013)
2013	$16,213,338 (10/1/2013 through 9/30/2014)
2014	$16,351,717 (10/1/2014 through 9/30/2015)
2015	$16,057,192 (10/1/2015 through 9/30/2016)
2016	$15,797,509 (10/1/2016 through 9/30/2017)

Question 10: If funded through residential rates, for each of the past five years (2012-2016), what is the average spending/cost per residential customer in your state to support the CAP program?

New Hampshire:

Year	CAP Cost per Residential Customer
2012	0.0015 mills per kWh
2013	0.0015 mills per kWh
2014	0.0015 mills per kWh
2015	0.0015 mills per kWh
2016	0.0015 mills per kWh

Question 11: How do you define collections expenses for utility companies?

Colorado:

> Administrative costs are considered part of the cost included in the low-income program.

New Hampshire:

> Collection expenses are reviewed during rate cases, not as part of assistance programs or energy efficiency programs.

Ohio:

> Collection expenses are defined as the cost labor, materials, and expenses incurred in work on collections as recorded in the Federal Energy Regulatory Commission (FERC) 903 account during a rate case. Collection expenses may also include uncollectible expenses.

Question 12: Questions about utility collections expenses:

Colorado, New Hampshire, and Ohio track utility collections expenses. Only Colorado includes CAP expenses in their utility collections expenses.

None of these states reported seeing a corresponding reduction in utility collections expenses for increased enrollment of low-income customers in their CAP programs.

Only Colorado reported having different collections procedures for CAP, non-CAP low-income, and non-low-income residential customers. For low-income customers, expenses are included in the low-income program while all other collection expenses are included in base rates.

None of the responding states reported observing better payment patterns for low-income customers who are in CAP compared to low-income customers not in CAP.

Question 13: On the average over each of the past five years (2012-2016), what percent of monthly payments for CAP customers are paid in full?

Ohio

Percent of Monthly CAP Bills Paid in Full		
Year	**Electric**	**Gas**
2012	52%	50%
2013	52%	51%
2014	53%	53%
2015	55%	59%
2016	55%	59%

Question 14: For each of the past five years (2012-2016), what were the service termination rates?

Ohio:

Ohio CAP Termination Rates			
Year	**CAP Customers**	**CLI Customers**	**Non-CAP Residential**
2012	11%	**No Response**	3%
2013	17%	**No Response**	6%
2014	9%	**No Response**	5%
2015	3%	**No Response**	3%
2016	11%	**No Response**	5%

ABSTRACT

We study the residential demand for electricity and gas, working with nationwide household-level data that cover recent years, namely 1997–2007. Our dataset is a mixed panel/multi-year cross-sections of dwellings/households in the 50 largest metropolitan areas in the United States as of 2008. We estimate static and dynamic models of electricity and gas demand. We find strong household response to energy prices, both in the short and long term. From the static models, we get estimates of the own price elasticity of electricity demand in the −0.860 to −0.667 range, while the own price elasticity of gas demand is −0.693 to −0.566. These results are robust to a variety of checks. Contrary to earlier literature (Metcalf and Hassett, 1999; Reiss and White, 2005), we find no evidence of significantly different elasticities across households with electric and gas heat. The price elasticity of electricity demand declines with income, but the magnitude of this effect is small. These results are in sharp contrast to much of the literature on residential energy consumption in the United States, and with the figures used in current government agency practice. Our results suggest that there might be greater potential for policies which affect energy price than may have been previously appreciated.

1. Introduction

In the United States and in other developed countries, buildings account for over 40% of total annual energy use. Despite many recent policies that either mandate or promote energy efficiency among residential energy users,[1] U.S. residential energy demand has grown over the last three decades, and projections suggest that it will continue to do so for the foreseeable future (Energy Information Agency, 2010).

Recently, there has been considerable debate in academic and policy circles as to whether retail energy prices, including those charged to the residential sector, will increase or decrease as a result of deregulation (Fabrizio et al., 2007; Showalter, 2007a,b; Carlson and Loomis, 2008), establishment of emissions trading markets (e.g., Frondel et al., 2008; Burtraw et al., 2002; Smale et al., 2006), and imposition of renewable portfolio standards, which is usually done at the state level (Fischer, 2010). More stringent environmental regulations on emissions and pollutants from power plants (e.g., nitrogen and sulfur oxides, and mercury) and tightened ambient air quality standards are also expected to increase the cost of energy to consumers.[2]

For the purpose of forecasting demand and planning for generation, transmission and distribution capacity, and for energy policy purposes, it is important to measure the responsiveness of residential

[1] The American Recovery and Reinvestment Act (the Stimulus Bill) of 2009, for instance, allocated some $27.2 Billion for energy efficiency and renewable energy R&D. Yet, despite many cost-effective opportunities for energy efficiency improvement, projects often go unpursued. In principle, were homeowners aware of the future energy savings, they would spontaneously undertake energy efficiency investments in their homes. In practice, consumers and homeowners have often been observed to pass up opportunities to make energy-efficiency investments. Possible explanations for the so-called "energy paradox" (Jaffe and Stavins, 1994) include liquidity constraints, limited information, uncertainty about future energy prices (Hassett and Metcalf, 1993), high rates of intertemporal preferences, disbelief in engineering estimates of the cost savings themselves (Metcalf and Hassett, 1999), and institutional disincentives (see Golove and Eto, 1996).

[2] Financing costs from investments to electricity transmission and distribution infrastructure, volatility and rising scarcity in feedstocks such as coal, propane, natural gas, and petroleum, and the establishment of a price on carbon, are all possible mechanisms which would increase the price of energy (Basheda et al., 2006).

energy demand to the prices of electricity and gas, the two major sources of residential energy in the U.S. Earlier research has examined household demand for energy and its responsiveness to price, but these analyses i) used old data (Quigley and Rubinfeld, 1989; Metcalf and Hassett, 1999), ii) are restricted to limited geographical areas (e.g., Garcia-Cerrutti, 2000; Reiss and White, 2005), so that it is difficult to extrapolate their results to other areas with different climates, housing stock and electricity suppliers, or iii) were based on cross-sections or extremely short panels of data (with a maximum of two observations per household) (e.g., Metcalf and Hassett, 1999), and did not fully address issues of unobserved heterogeneity and endogeneity. In some cases, responsiveness to price was inferred from supply shocks so severe and geographically circumscribed (e.g., Bushnell and Mansur, 2005; Reiss and White, 2008) as to render them inapplicable for broader areas and more gradual price changes.

For these reasons, in this paper we wish to ask three research questions. First, what *are* the (nationwide) price elasticities of residential electricity and gas demand? Second, is such responsiveness sensitive to equipment and energy choices that are not easily reversed (e.g., using gas or electricity for heating or cooling)? Third, how does household income influence demand and the price elasticities?

We use energy utility data for over 69,000 single-family homes and duplexes (74,000 households) in the 50 largest metropolitan areas in the US for 1997–2007, and estimate static and dynamic models, with and without controls for the current stock of appliances. Unobserved heterogeneity is accounted for using fixed effects at various levels (at the city, dwelling and dwelling-household level). Briefly, we find that electricity use is responsive to the price of electricity (with an elasticity that ranges from −0.67 to −0.86) and increases with the price of gas, indicating that the latter is a substitute for electricity. The demand for gas is only slightly less responsive, with own-price elasticities ranging from −0.565 to −0.693. The elasticities are highest in the models with city-specific effects, and lowest in the models with dwelling-specific effects, but stay within a limited range. (Accounting for unobserved heterogeneity reduces the elasticities by 15% to 32% relative to a model that does not include any effects at all, where the own price elasticity of electricity demand is −1.).

The price elasticities are stable across specifications, and similar for homes with electric and gas heat. Our checks suggest that the effect of mismeasuring energy prices is small. The price elasticities are slightly higher among the poorest households (those that fall in the bottom 25% of the distribution of household income in our sample), and decline monotonically with income, but in practice this effect is not important. Our dynamic models produce short-run own-price elasticities equal to −0.736 and −0.572 for electricity and gas, respectively. Their long-run counterparts are −0.814 and −0.647, respectively. These figures are virtually unchanged whether or not we control for difficult-to-reverse choices of heating/cooling technologies.

The remainder of the paper is organized as follows. We offer a brief literature review in Section 2. We describe the models and econometric issues in Section 3 and the data in Section 4. Section 5 presents the results, and Section 6 offers concluding remarks.

2. Previous literature

Knowing the responsiveness of energy demand to the price allows analysts to predict the effects of price changes or policies that result in price changes—for example, taxes on carbon emissions, or mandates on the share of renewable energy. Earlier research has produced a wide range of estimates of the price elasticity of demand in the residential sector, possibly because of the diverse types of data used (time-series, cross-sections and panel), level of geographical and jurisdictional aggregation (local, state, or national), extent of the observed variation in price, and time periods covered.

We summarize selected studies in Table 1. These include studies based on annual time-series aggregates for the entire US, such as Dergiades and Tsoulfidis (2008), who estimate the short- (long-) run own-price elasticity of residential electricity consumption to be −0.386 (−1.06), and Kamerschen and Porter (2004), where the elasticities range from −0.94 to −0.85. Studies based on recent state-level panel data, such as Bernstein and Griffin (2005), Paul et al. (2009), and Alberini and Filippini (2010), have often found that the demand is relatively insensitive to price, at least in the short term, and that the estimates of the long-run elasticity are very sensitive to the specific estimation procedure.[3] Garcia-Cerrutti (2000) uses county-

[3] For example, Alberini and Filippini (2010) use annual state-level data in the U.S. from 1995 to 2007, and attempt to get consistent estimates of the long-run elasticity by using a bias correct "within" estimator (Kiviet, 1995) and the Blundell and Bond (1998) approach. The short-run own price elasticities of electricity range from −0.15 to −0.08, and their long-run counterparts range from −0.78 to −0.44.

level data from 44 California counties for 1983–1997, estimates the own-price elasticity of electricity demand to be −0.17 in the short run and −0.19 in the long run, and uncovers significant variation between counties.

Most household-level data studies are limited in either time coverage or geographic scale. Quigley and Rubinfeld (1989) use a cross-section from the 1980 American Housing Survey and find evidence of low elasticity of energy demand (−0.1 in the short run). Metcalf and Hassett (1999) use the 1984, 1987 and 1990 waves of the Department of Energy's Residential Energy Consumption Survey (RECS) to examine homeowners' insulation investments, finding price elasticities of electricity ranging from −0.73 to −1.16.

Bernard et al. (2010) have multi-year cross-sections about electricity and gas consumption and prices in Quebec from 1989 to 2002, estimate the short-run and long-run elasticity to be −0.51 and −1.32, respectively, and conclude that electricity and natural gas are substitutes.[4] Reiss and White (2005) focus on the California households in RECS, match each household with the block pricing structure applied by the utility that serves each area, and estimate a model of choice of block and consumption levels using GMM.

One concern when examining the responsiveness of electricity use with respect to price is that the data contain sufficient price variation. Such variation is usually attained by selecting a broad geographic area and/or a sufficient long period of time. In some cases, identification is made possible by abrupt changes in prices due to supply conditions. Reiss and White (2008) and Bushnell and Mansur (2005) exploit the energy crisis and rapidly growing electricity rates in California in 2000 and 2001, and document relatively large reductions in energy usage induced by such price increases. Haas and Schipper (1998) argue that energy-saving investments spurred by raising prices are likely to remain in place even in periods of declining energy prices, but in practice there is reason to question the external validity of findings based on unusual market circumstances at specific locations.

In this paper, we avoid these concerns by following a nationwide sample of dwellings over ten years, and augmenting these data with multi-year cross-sections of households from the same metropolitan areas. To conduct our analyses, we must assign the correct energy price to each household, but doing so is not straightforward.

There is considerable debate in the literature whether household energy demand depends on the marginal or average price, which may differ in the presence of fixed fee and block pricing. Shin (1985) argues that households will respond to average price, which is easily calculated from the electricity bill, rather than to the actual block marginal price, which is costly to determine, and develops an empirical strategy for testing this conjecture. The average price is also used in Metcalf and Hassett (1999),[5] and Borenstein (2008, 2009) and Ito (2010) find no evidence that consumers "bunching up" around the block where the price changes, as one would expect if consumers truly respond to marginal price. If demand is assumed to depend on the marginal block price, then price and consumption are simultaneously determined, and instrumental variable estimation techniques must be used (Burtless and Hausman, 1978; McFadden et al., 1978; Wilder and Willenborg, 1975; Hewitt and Hanemann, 1995; Reiss and White, 2005).

For lack of exact information about the block rates faced by the consumers, however, we are forced to use average price. We impute to each household the average price per unit of electricity or gas charged by the utilities in the area. This measure of price is exogenous to the household, but is affected by measurement error. We discuss this issue in Section 3.3 below. An additional concern is whether usage decisions depend on the price in the current (billing) period, on that of earlier periods, or a moving average of the prices of recent periods (Poyer and Williams, 1993). For good measure, in what follows we experiment with current price, as well as price of the previous period.

3. The models and econometric estimation issues

3.1. Two models of residential energy demand

In this paper, we focus on the demand for gas and electricity, because they are the most important fuels used by households in the U.S. Electricity is used by virtually 100% of the households, and gas serves 60% of the households. Fuel oil (7% of the households), LPG (1.5%) and kerosene (1.5%) are less important.[6]

We estimate two sets of models. In the first set, our regression equations are variants of the static energy demand model:

$$\ln Q_{it}^{(j)} = \beta_0^{(j)} + \beta_1^{(j)} \ln P_{E,it} + \beta_2^{(j)} \ln P_{G,it} + \mathbf{x}_{it}\boldsymbol{\gamma}^{(j)} + \tau_t + \varepsilon_{it}^{(j)} \tag{1}$$

where $j = \text{E, G}$ for electricity and gas, respectively, i denotes the dwelling, and t denotes the time period. Q is consumption, P denotes price, and the coefficients on the log prices are the short-term own- and cross-price elasticities.

Vector $\mathbf{x}$ is comprised of dwelling and household characteristics thought to influence the consumption of energy, such as weather, size and age of the home, heating and cooling equipment dummies, and appliances. For example, a house heated only with an electric heater would have a higher electricity demand than an identical home with gas heat. Household characteristics included in $\mathbf{x}$ are the number and age of occupants, income, the presence of children or elderly persons,[7] and a homeownership dummy. Eq. (1) includes year effects (the τs), and is easily amended to include dwelling or city-specific effects to account for unobserved heterogeneity.[8]

It is of interest to assess how consumption changes if individuals are allowed to adjust their stock of appliances and make energy efficiency and conservation investments. A partial-adjustment model (Houthakker, 1980) lets individuals adjust their stock of appliances and energy-efficiency investments. This model assumes that the change in log actual demand between any two periods ($t-1$ and t) is only some fraction (λ) of the difference between log actual demand in

[4] Studies outside of North America tend to be produce price elasticity ranges similar to those for North America. Nesbakken (1999) focuses on the choice of heating and residential energy consumption in Norway, reporting that short- and long-term price elasticities (in the range of −0.33 to −0.66) are remarkably stable across the 1990–1995 period, with the only exception of 1993. In contrast to other papers, responsiveness to price is more pronounced at higher levels of income. Rehdanz (2007) examines expenditures for residential space heating in Germany, and Meier and Rehdanz (2010) use a 15-year panel of residential heating expenditures in Great Britain. Using a log-linear specification with year and regional effects, they obtain gas price elasticities between −0.4 and −0.49, which fall in the range of −0.2 to −0.57 from the comparable literature. They obtain different elasticities for homeowners and renters. Leth-Petersen and Togeby (2001) find much lower price elasticities in heating fuels (on the order of −0.1) based on a panel dataset from Denmark and a conditional logit fixed-effect model.

[5] When the average price is computed from the consumer's bill divided by quantity, as is the case in Metcalf and Hassett (1999), it is endogenous with quantity.

[6] EIA, http://tonto.eia.doe.gov/energyexplained/index.cfm?page=us_energy_homes (last accessed 28 Sept. 2010).

[7] Earlier literature has examined the effect of age, race and ethnicity on energy demand. Poyer and Williams (1993) find that while the demand is inelastic for all groups, blacks appear to be more sensitive to short-run price variations than Hispanics and whites. Liao and Chang (2002) find that the elderly require more natural gas and fuel oil but less electricity, the demand for space heating increases as the elderly get older, and the demand for energy for heating water decreases with age.

[8] A special case of this situation is when the dwelling-specific effects are suppressed, but the error terms in the demand for electricity and gas equations are correlated within the same dwelling unit in the same period (but uncorrelated in different period and across dwellings). If so, the equations for log $Q^{(E)}$ and log $Q^{(G)}$ are part of a system of seemingly unrelated regression equation. Since the regressors are the same in the equations for log electricity and gas consumption, the most efficient estimation technique (GLS) is simplified to OLS applied separately to each equation.

period $t-1$ and the log of the long-run equilibrium demand in period t, Q_t*. Formally,

$$\ln Q_t - \ln Q_{t-1} = \lambda(\ln Q_t^* - \ln Q_{t-1}), \tag{2}$$

where $0<\lambda<1$. The dwelling subscript i and the electricity or gas equation superscript j are omitted to avoid clutter. This implies that given an optimum, but unobservable, level of energy consumption, demand only gradually converges towards that optimum level between any two time periods.

Assume that desired energy use (for example, desired electricity consumption) can be expressed as $Q_t^* = \alpha \cdot P_E^{\eta} \cdot P_G^{\theta} \cdot \exp(\mathbf{x\gamma})$, where η and θ are the long-term elasticities with respect to the price of the electricity and that of gas, and $\mathbf{x}$ is the vector of variables influencing demand for energy, including income, climate, characteristics of the stock of housing, income, etc. On inserting this expression into Eq. (2), we get

$$\ln Q_t - \ln Q_{t-1} = \lambda \ln \alpha + \lambda\eta \ln P_E + \lambda\theta \ln P_G + \lambda\mathbf{x\gamma} - \lambda \ln Q_{t-1}. \tag{3}$$

On re-arranging and appending an econometric error term, we obtain the regression equation:

$$\ln Q_t = \lambda \ln \alpha + \lambda\eta \ln P_E + \lambda\theta \ln P_G + \mathbf{x}\lambda\boldsymbol{\gamma} + (1-\lambda) \ln Q_{t-1} + \varepsilon \tag{4}$$

Eq. (4) shows that the short-run elasticities are the regression coefficients on the log prices, whereas the long-run elasticities can be computed by dividing these short-run elasticities (i.e., the coefficients on the log prices) by the estimate of λ. In turn, the latter is easily obtained as 1 minus the coefficient on $\ln Q_{t-1}$.

3.2. Estimation of the dynamic model

We wish to estimate the partial adjustment model (Eq. (4)) with fixed, dwelling-specific effects. One concern with this specification is that the lagged dependent variable in the right-hand side may be serially correlated and hence correlated with the error term, which makes the LSDV and GLS estimators biased and inconsistent, since $\left(y_{i,t-1} - \overline{y}_{i,-1}\right)$, where $y_{i,t-1} = \ln Q_{i,t-1}$ and $\overline{y}_{i,-1}$ is the average of the $y_{i,t-1}$s for unit i, is correlated with $\left(\varepsilon_{i,t} - \overline{\varepsilon}_i\right)$ (see Baltagi, 2001). The bias vanishes as T gets large, but the LSDV estimator remains biased and inconsistent for N large and T small, as is the case here, since we have tens of thousands of homes but the maximum length of the longitudinal component of the sample is 6.[9]

Kiviet (1995) derives an approximation for the bias of the LSDV estimator when the errors are serially uncorrelated and the regressors are strongly exogenous, and proposes an estimator that is derived by subtracting a consistent estimate of this bias from the LSDV estimator. An alternative approach is to first-difference the data, thus swiping out the state-specific effects:

$$\Delta y_{it} = \gamma \cdot \Delta y_{i,t-1} + \Delta \mathbf{w}_{it}\boldsymbol{\beta} + \Delta\varepsilon_{it} \tag{5}$$

where $\mathbf{w}$ denotes all exogenous regressors in the right-hand side of Eq. (4), and to use $y_{i,t-2}$ and Δw_{it} as instruments for $\Delta y_{i,t-1}$ (Anderson and Hsiao, 1982).

Arellano and Bond (1991) point out that the latter approach is inefficient and argue that additional instruments can be obtained by exploiting the orthogonality conditions that exist between the lagged values of $y_{i,t}$ and the disturbances. The Arellano–Bond procedure is a generalized method of moments (GMM) estimator that is implemented in two steps. In practice, the Arellano–Bond estimator has been shown to be biased in small samples, and the bias increases with the number of instruments and orthogonality conditions. Moreover, Arellano and Bond (1991) show that the asymptotic approximation of the standard errors of their two-step GMM estimator is biased downwards, and they, as well as Judson and Owen (1999), find that the one-step estimator outperforms the two-step estimator.

Under the additional assumption of the quasi-stationarity of $y_{i,t}$, $\Delta y_{i,t-1}$ is uncorrelated with ε_{it}, and Blundell and Bond (1998) suggest a "system" GMM estimation where one stacks the model in the levels and in the first differences, imposes the cross-equation restriction that the coefficients entering in the two models be the same, and uses the full set of instruments (corresponding to the full set of orthogonality conditions for both models). Blundell and Bond report that in simulation the "system" GMM estimator is more efficient and stable than the Arellano–Bond procedure. This is the approach we adopt for the partial adjustment model.

3.3. Mismeasured prices

As we explain in more detail in Section 4, in this study the price of energy is measured with an error, because we do not know the exact price(s) faced by the household and impute the average price paid by residential customers in that area. The standard econometric theory shows that when a regressor is mismeasured, and the measurement error is classical, the estimated regression coefficient is downward biased (Greene, 2008, page 325–326). In our case, we must keep in mind that the mismeasured price enters in the construction of the dependent variable as well as in the right-hand side of the model as a regressor.

Alberini et al. (2010) discuss the implications of mismeasured prices, assuming for simplicity that only own price in entered in the right-hand side of Eq. (1). Specifically, if the measurement error is approximately constant within a dwelling over time, then it is eliminated by the LSDV procedure, and one obtains consistent estimates of the slopes. If the measurement error is classical (i.e., completely uncorrelated within and between the units in every period), then the price elasticity will be overstated (i.e., the absolute value of the estimated coefficient will be greater than $|\beta_1|$).[10]

How can one get around the mismeasurement problem? One approach is to restrict estimation to areas where mismeasurement is likely to be less severe (e.g., areas with only one utility). Another is to instrument for $\ln p^*$, which we do using state-level electricity and gas prices, or, in alternate runs, lagged electricity prices.

4. The sample and the data

4.1. The Data

In addition to data provided by individual utilities for their service territories (e.g., Borenstein, 2008, 2009) or otherwise geographically circumscribed areas (e.g., Shin, 1985; Garcia-Cerrutti, 2000; Bushnell and Mansur, 2005), earlier research has used the Department of Energy's Residential Energy Consumption Survey (RECS) to examine energy use patterns at the household level (e.g., Metcalf and Hassett, 1999; Reiss and White, 2005). Despite its national coverage, we were dissatisfied with this dataset, because it does not lend itself to panel data modeling (the length of the longitudinal component is at most

[9] We remind the reader that, when attention is restricted to those dwellings that appeared in more than one round of AHS survey, we have an unbalanced panel with T ranging from 2 to 6. A similar argument applies if we use dwelling-household effects instead of dwelling effects.

[10] Alberini et al. (2010) also examine whether it is possible to identify the price elasticity by exploiting the fact that the log real price, which appears in the right-hand side of Eq. (1), is the log of nominal price minus the log of the price index. They show that if only log nominal price and log price index are uncorrelated is it possible to obtain an unbiased estimate of the price elasticity. This is not the case here, since in this dataset log nominal price and log price index are positively correlated.

[a] Eligible because of unambiguous state identification in the AHS.

2), and the geographical identification is at too coarse a level to link each household with the relevant utilities (or to state-level or local policies or incentives).[11]

For these reasons, we assembled a large and comprehensive dataset that merged several sources of data. We use the American Housing Survey (AHS), a longitudinal study conducted by the Department of Housing and Urban Development where the cross-sectional units are dwellings (not households). The AHS contains extensive information about the structural characteristics of the dwelling, renovations and retrofits, home ownership and its financial aspects (mortgages, maintenance costs, etc.), appliances and heating/cooling systems, socio-demographic and economic circumstances of the occupants, and their assessment of the quality of the home and the neighborhood.

We focus on "national" survey AHS data for 1997, 1999, 2001, 2003, 2005, and 2007, which means that we can follow homes for up to $T=6$ periods. We augment this sample with observations from the AHS "metro"[12] surveys, which are conducted in even years in specific areas. We use the 2002, 2004 and 2007 metro surveys. Homes in the metro surveys are surveyed only once, so our sample is a mix of panel data plus multi-year cross-sections.

Because of privacy concerns, the AHS discloses the location of the dwelling only if the area has a population of 100,000 or more. We selected dwellings in the 54 cities corresponding to the 50 largest metropolitan areas in the U.S. as of 2008, unless the AHS SMSA identification makes it impossible to identify unambiguously which state the dwelling is located in. Table 2 lists the "candidate" metro areas (the 50 largest in the U.S. as of 2008) and indicates which are included in our study. These locations should ensure considerable variation in climate, age of the stock of housing and construction materials (which may affect efficiency of space heating and cooling), and utility prices.

Our sample is restricted to single-family homes and duplexes. We further restrict attention to homes that are owner-occupied or occupied by a tenant, and where these persons actually are responsible for paying the utility bills.[13] These criteria yielded a sample size of 120,333 observations. We deleted observations where i) the home was occupied as a residence for only part of the year, ii) the utility bills had been imputed using "hot deck" procedures, iii) the square footage (which should be an important determinant of energy usage) had been imputed using "hot deck" procedures, and/or iv) large and implausible changes in size were observed from one time period to the next.[14] This left us with 98,774 observations, which are further reduced to 98,772 when we further exclude residences where the heating equipment is shared with other units (2 observations).

Table 3 displays the distribution of this final sample by city. Table 4 summarizes information about the longitudinal component of our sample, examining the case where the cross-sectional units are the dwellings, and that where the cross-sectional units are dwelling-families. We have a total of 69,169 homes and 74,697 households (because families may move into and out of any given home during the study period).

4.2. Energy consumption and utilities' rates

The AHS reports the average monthly utility bill (and annual payments on heating oil fuel for those households that use heating oil) in the survey year, but does not report the electricity or gas tariffs, nor the actual energy consumption (in kilowatt-hours [kWh] or thousand cubic feet [MCF]).

[11] RECS provides the Census Region for each household. It provides the state identifier only if the household resides in one of the four most populous states (California, New York, Texas and Florida). HDD and CDD information is provided, but the true figures at the household's location are masked to ensure confidentiality.

[12] The Nationwide AHS sample returns to the same homes for every survey, and adds some newly constructed homes to keep the sample representative of the housing stock in the U.S. The metro surveys are conducted on a representative sample of homes in different cities every two years, but in the metro surveys different homes are selected in different waves for the same city.

[13] In other words, we exclude tenants where the utilities are included in the rent. Incentives to save on utilities may be different in this case.

[14] Specifically, we excluded observations with a change in the amount of energy or gas used that changed by more than 500% from one period to the next, while at the same time no renovation in the home and no square foot change was reported. Homes that experienced a change in square footage of more than 1000% from one period to the next, or with a change in square footage of more than 100% without a reported renovation to the home, were also discarded.

Table 3
Distribution of the sample by city. N = 98,772.

City	Nobs	Percent	City	Nobs	Percent

Milwaukee	2295	2.32	West Palm Beach	339	0.34

We must therefore construct consumption by taking the bills and dividing them by unit price. Unfortunately, the names of the utilities and the rate structure are not identified in the AHS either, so we were forced to impute average tariffs per kWh and cubic foot of gas for each dwelling in a number of ways.

For each metropolitan area, we identified the relevant gas and electric utilities using the listings provided by the state public utility commission, and a variety of on-line city services. We also consulted the list of counties covered by each utility, as documented in the Energy Information Agency (EIA) 861 forms database. We obtained utility-level price information from the EIA 861 forms (for electricity) and EIA 176 forms (for gas), which the utilities are required to file every year with the agency. Next, if the area was supplied by a single utility, we computed the average price per kWh (MCF) as the utility's annual revenue from sales to residential customers divided by the kWh (MCFs) sold to residential customers.[15]

If the area was supplied by more than one utility, we first computed the average price charged by each of them in the aforementioned fashion, and then constructed three alternative measures of price to use in our regressions. One, which we dub “residential price 1,” is a weighted average of each utility's average tariff per kWh, where the weights are proportional to the utility's customer base. The next, which we dub “residential price 2,” is also a weighted average, with weights assigned to represent the utility's dominance of the market.[16] The final constructed price (“residential price 3”) is a simple average of the individual utilities' average tariffs.[17] We followed a similar approach for gas utilities.

We use the prices of electricity and gas in two ways. First, we use them to create the dependent variables in our regressions: consumption of electricity and gas are obtained as the amount on the bill divided by (nominal) price. Second, (real) prices enter in the right-hand side of the demand equations.

[15] We note here that the EIA computes state-level electricity prices and gas prices exactly in this fashion—by taking the revenues of all utilities and dividing by all kWhs (or gas) served to residential households.

[16] If a utility dominates the market completely, despite the nominal existence of other utilities, that utility received a weight of ones and the others weights equal to zero. If two utilities were perceived to share the market in the area in a relatively equitable fashion, we assigned weights of 0.5 to each.

[17] Clearly, if there is a single utility, residential price 1, 2 and 3 are all identical.

Table 4
Distribution of the sample by length of the longitudinal component. N = 98,772.

	Unit: dwelling		Unit: dwelling-family	
T (length of the panel)	Freq.	Percent	Freq.	Percent
1	58,088	58.81	63,916	64.71
2	7094	7.18	9616	9.74
3	5315	5.38	6126	6.2
4	8232	8.33	6236	6.31
5	10,905	11.04	6740	6.82
6	9138	9.25	6138	6.21

We note here that, technically speaking, these average prices are not necessarily equal to the prices faced by the households. The majority of the utilities apply block pricing, but with such a geographically broad sample and such a long study period, it would be unfeasible to obtain the block pricing schemes used by each utility in each period. The only remaining econometric concern is that the price we use in our regression is measured with error. With our model and data construction, as explained in Section 3.3, this would make the household demand appear to be more elastic than it truly is.

We display descriptive statistics about prices and energy use in Table 5. Attention is restricted to the “price 1” variables because the others were very close to them.[18] Every home is served by electricity, and, as shown in Table 5, on average our households use about 930 kWh per month. This is in line with nationwide estimates collected by the Department of Energy using a dedicated survey (RECS). Just over three-quarters of the sample (76.6%) use natural gas as well, and almost 88% of such natural-gas connected households use gas heat. In a typical month, gas usage is 7.27 MCF.

Over the study period, the average price of electricity is about 11 cents per kWh (2007$). We found, however, evidence of considerable variation across states. The state with the lowest prices is Indiana (about 6.8 cents per kWh on average over the study period) and that with the highest prices is New York, where a kWh averaged almost 18 cents over the study period (2007$). The price of natural gas exhibits similar variability across locales. The average price per MCF is $11.41 (2007$), with Georgia exhibiting the lowest prices ($6.10, 2007$, on average) and Florida the highest ($17.83, 2007$).

Since we exploit the longitudinal feature of our data, it is important to check the extent of the variation in prices across and within units. In what follows, the units are the dwellings. We computed the total variation of real electricity prices and of log real electricity prices, and found that in each case the variation within dwellings accounted for only 4% of the total variation.[19] Gas prices are more variable over time: the “within” dwelling variation accounts for about 14% of total variation in real gas prices, and 15% of the total variation for log real gas prices.

4.3. Other key regressors

The weather is an important determinant of energy use. We computed heating and cooling degree-days (HDDs and CDDs) in the year prior to the date of the AHS survey using the T3 Global Summaries of the Day from NOAA's National Climatic Data Center. We matched each metro area with the T3 monitors in that area, computed

[18] The correlation coefficients between the “price 1” variables and the others were generally higher than 0.97.

[19] Our measure of variation is the sum of square deviations from the grand mean.

Table 5
Prices and monthly consumption of electricity and natural gas.

Variable label	Description	Obs	Mean	Std. dev.	Min	Max
kWh 1	Monthly electricity usage (kWh)	97,344	930.39	654.09	11.06	5697.54
gasuse1	Monthly gas usage (MCF)	67,154	7.27	5.50	0.23	71.86
residentialprice1_r	Price of electricity per kWh (2007 dollars)	98,487	0.11	0.03	0.05	0.22
gasprice1_r	Price of natural gas per MCF (2007 dollars)	94,315	11.42	3.10	3.90	22.89
Log kwh1		97,344	6.61	0.70	2.40	8.65
Log gasuse1		67,154	1.75	0.68	−1.49	4.27
Log residentialprice1_r		98,487	−2.23	0.26	−2.92	−1.49
Log gasprice1_r		94,315	2.40	0.26	1.36	3.13

the average of the mean temperatures for each day of the year prior to the date of the survey, created the HDD (CDD) for that day as 65 °F minus the average temperature (average temperature minus 65 °F), and summed over the year prior to the survey. This construction is the same as that used by the U.S. Department of Energy. The average HDDs and CDDs are 3450 and 1658 degree-days, respectively.

Our regressions control for dwelling characteristics, such as the age and size of the home, number of rooms, and number of floors, which come from the AHS. We enter all continuous variables in log form in the regression. Descriptive statistics for these variables are displayed in Table 6. The average size of the home is about 2000 square feet. This figure matches up nicely with the nationwide estimates for single-family homes and homes that are part of a two-unit building from the 1997, 2001, and 2005 RECS.

Despite removing observations with imputed square footage and implausible changes in square footage from one survey wave to the next, our sample does contain some observations with extremely small and extremely large values for size and the number of floors, so in our regressions we further restrict attention to homes no smaller than 400 square feet and no larger than 10,000. We also delete from the usable sample homes with more than 4 floors (single family homes are unlikely to have 5 or more floors).

Descriptive statistics for this cleaned sample are reported in the bottom panel of Table 6. The average square footage, house age and number of rooms are virtually unchanged. We note that a value of zero for the age of the house is correct: it means that the home was built in the same year of the survey. (The AHS does add new dwellings to mirror the stock of housing and new constructions. Homes with age 0 account for less than 1% of the sample.)

We report descriptive statistics about heating and cooling equipment, as well as appliances that use energy, in Table 7. All of this information comes from the AHS. Briefly, in terms of heating, about 67% of the sample has a gas heating system, 26% relies on electricity for heating, and about 5% on heating oil as the main source of heat. Homes with electric heat are located primarily in states with mild or warm climates, such as Arizona (66% of all Arizona homes), Florida (93.80%), Louisiana (43%), Tennessee (59%) and Texas (43.76%), or cheap electricity (e.g., Washington, 29%).

About 84% of the sample has some type of air conditioning, and about 67% has central air conditioning. Window units are used by 20% of the sample, sometimes alongside with central air conditioning. Only 2% of the observations have gas-powered heat pumps. Turning to appliances, virtually all homes have a fridge, almost 72% a dishwasher, 32% use gas-powered clothes dryers, and a little more than half of the sample has an electric stove.

Summary statistics of household characteristics are shown in Table 8. Briefly, we find that the average household income over the study period is about $88,000 (2007$). There are a small number of households (93, or 0.09%) that report negative income. When these persons are removed, the distribution of household income is essentially unchanged: The new sample average is still $88,000 (2007$).[20] The average household size is 2.8, 31% of the sample has small children, 22% has at least one person aged 65 or older living in this house, and almost 84% owns the home.

5. Results

5.1. Static models

Results for several specifications of the static model (see Eq. (1)) are reported in Table 9 for log electricity consumption, and in Table 10 for log gas consumption. The runs differ for the type of effects we include to account for unobserved heterogeneity.

We choose to report results for fixed city-, dwelling- and dwelling-family specific effects. We include city-specific effects because 1) the coefficients on most regressors are similar to those from a random effects model with dwelling-specific effects (estimated using GLS), 2) it stands to reason that homes and residents might share similar unobservable characteristics as other homes and residents in the same metro area, 3) we do not lose the observations with $T=1$, and 4) we are able to assess the impact on consumption of factors that vary widely across locales (e.g., home size, income, etc.) but little within a house over time. Finally, 5) assigning average prices at the metro-area level to each dwelling likely produces errors that are correlated within the metro area, biasing standard error estimates downward (Moulton, 1990). For this reason, we cluster the standard errors at the city level.

Fixed dwelling effects are a natural candidate, since the AHS follows a dwelling over time, while dwelling-family effects allow for unobservable heterogeneity to depend on the household as well as the home.[21] We prefer fixed effects because Hausman tests indicate that if the unobserved heterogeneity is modeled using random effects, these are correlated with the included regressors, which makes the GLS estimates inconsistent. For good measure, the standard errors are clustered at the city level (in specifications with city effects) or at the dwelling level (in specifications with dwelling and dwelling-household effects).

[20] In our regressions, which use log income, we will simply recode log income to zero when income is negative.
[21] The fixed effects also account for any selection of households into cities or homes.

Owner (dummy)	98,772	0.84	0.37	0	1

Starting with Table 9, most of the coefficients are significant and have the expected sign. Importantly, column (A) – the results of a model with city-specific effects – shows that the elasticity of electricity use with respect to the price of electricity is −0.860, and the cross-elasticity with respect to the price of gas is positive and equal to 0.117, indicating that the two are substitutes.[22]

Consumption of electricity increases by 22% for every 10% increase in the square footage of the home, is 16% higher if the home has air conditioning, and about 15% higher if the home is heated using electricity. Dishwashers and electrical stoves increase usage by 8% and 7%, respectively (not displayed in the table). F tests reject the null hypotheses that heating/cooling systems are jointly equal to zero (F statistic = 37.65, p value less than 0.0001) and that the appliances are not associated with electricity consumption (F statistic = 38.05, p value less than 0.0001).

The income elasticity of electricity consumption is only about 0.02. One reason for such a low elasticity might be the fact that income is highly correlated with characteristics of the home, such as the size, the number of floors, and the presence of certain appliances. Once we removed these from the specification, income elasticity of electricity usage increased to almost 0.05.

Column (B) presents the results of a FE specification where the cross-sectional units are the homes. The own price elasticity is lower (−0.667), as expected, but the cross-price elasticity is slightly stronger. As expected, the coefficients on most other variables are much smaller than their counterparts in the city-specific effects specification, because these variables rarely change within a home over time. In column (C), we present the results of a model with dwelling-household specific effects. They are similar to those in column (B), with slightly stronger own- and cross-price elasticities.

As to the gas equation, columns (A)–(C) of Table 10 show that the own price elasticity ranges from −0.693 (city-specific effects) to −0.565 (dwelling-specific effects). The model with dwelling-household effects produces a price elasticity of −0.577. The cross-price elasticity is positive (0.150) and indicates that gas and electricity are substitutes in the model with city-specific effects (column (A)), but turns insignificant when we use dwelling-specific effects, and negative and insignificant in the model with dwelling-family effects.

The model with city-specific effects indicates that gas usage increases by 19% for every 10 percentage point increase in the square footage of the home, and is about 24% larger in homes with gas heating systems. The impact of these variables is small and statistically insignificant in the variants with dwelling- and dwelling-household effects.

5.2. Robustness checks

Our first order of business is to examine the size of the potential bias due to measurement errors in the prices of electricity and gas. To see if such a bias is severe, we began with regressions where the sample is restricted to metro areas served by one utility. We argue that the measurement error due to our price imputation procedure is smaller in single-utility areas. For electricity usage, the results of these runs are reported in columns (D) and (E) of Table 9 for the models with dwelling-specific effects and dwelling-family effects. Similar models for gas usage are displayed in columns (D) and (E) of Table 10. Clearly, the own-price elasticities are very close (and slightly higher than) to their counterparts in columns (B) and (C).

Next, we estimated a log kWh model with fixed dwelling-specific effects, the regressors as in Table 9, and log electricity price (but no gas price). If we do not instrument for electricity price, the own price elasticity is −0.6794. When we instrument for log electricity price using the log of the state average prices of electricity and gas as the identifying instruments, the coefficient on log price is −.67907.[23] Using log state-level electricity price as the only identifying instrument produces an own price elasticity of electricity demand of −0.6584, while replacing that with the first lag of log price of electricity in the metro area yields an elasticity of −0.6108.

Finally, we estimated a model where the dependent variable is the log electricity bill, the right-hand side includes fixed dwelling-specific effects, all other controls, the log of nominal electricity price and the log of the CPI (but no gas price).[24] The coefficient on log nominal electricity price is 0.3223 and that on log CPI is 0.5981. The corresponding estimates of the elasticity with respect to the price of electricity are −0.6777 and −0.5891 (from the coefficient on log price and log CPI, respectively). Although we argue in Section 3.3 that these are both likely to overstate the true elasticity, they are within 10–15% of the original estimates and of the IV estimates of the price elasticity, suggesting that the impact of measurement error is modest.

Observers sometimes speculate that high price elasticities might be capturing the effect of conservation and energy efficiency installations made possible by the utilities' DSM initiatives.[25] We do have the DSM expenditure per customer by the electrical utilities that serve any given metro area, and, indeed, it is indeed positively correlated with electricity price (correlation coefficient 0.28). However, when we add DSM expenditure per customer (in real terms) in the right-hand side of the log kWh model, the coefficient on log electricity price is virtually unchanged (−0.657).

To check if consumption depends on current or recent prices, we also estimated models similar to the ones shown in Tables 9 and 10, but where we further included lagged prices. We found that i) the

[22] It is useful to compare these figures with their counterparts in an OLS regression that ignores unobserved heterogeneity. The own price elasticity when the city effects are suppressed is −1. Adding state effects (but no city effects) makes it −0.894.

[23] Our instruments are in the spirit of Black and Kniesner (2003), who propose using another mismeasured variable (i.e., state-level annual average prices) to clean out the measurement error in the original mismeasured regressor (here, average price in the metro area).

[24] This model is obtained on recognizing that i) log kWh is equal to log bill minus log nominal price, and ii) in the right-hand side of the demand equation, log real price is equal to log nominal price minus log CPI.

[25] We are grateful to Mark Jacobsen, personal communication, 2010, for raising this issue.

coefficients on contemporaneous price were strongly significant and similar to their counterparts in Tables 9 and 10, and ii) the coefficients on lagged prices were very small in magnitude and insignificant at the conventional levels. This is unsurprising if we recall that the "previous period" is usually two years prior to the current observations. We would expect people to react to changes in recent billing periods, and billing periods are usually one month (see Reiss and White, 2008).

To make that our results are not driven by outliers, we experimented with trimming the sample, e.g., we excluded the observations in the bottom and top 1%, 2.5%, etc. of the distribution of kWh s and MCFs. The elasticities and most other coefficients remained virtually the same as those in Tables 9 and 10.

In columns (F) and (G) of Tables 9 and 10, we report regression results for the subsamples with electric heat and gas heat. We report only the results for the models with city-specific effects for the sake of brevity, but the same qualitative results hold for the models with dwelling- and dwelling-households effects (although the magnitude of the coefficients is slightly smaller). In contrast to earlier literature (Metcalf and Hassett, 1999; Reiss and White, 2005), we find households with electric heating systems are actually *less* responsive to the price of electricity than households that use gas heat. Households with gas heat are slightly *more* sensitive to the price of gas than households that use electric heat.

However, Wald tests of the null that the elasticities are the same across the two groups fail to reject the null. For example, if attention is restricted to the equations in columns (F) and (G) of Table 9, the Wald statistic of the null of identical own price elasticities is only 1.13 (p-value 0.29).

The Wald statistics are even smaller in runs with fixed dwelling (or dwelling-household) effects. One possible explanation for this is that the sample size is rather uneven across the groups of homes served with electric and gas heat. The number of observations with electric heat is 23,542, but drops to 8416 when only true "panels" are used. This is only about 8% of the total sample. The resulting increase in variance may help explain the lack of significant differences across the two subsamples.

Finally, we estimated models where we allow the responsiveness to energy prices to vary with the quartile of the income distribution that the household falls in. We find that the responsiveness to prices is a bit higher in the first quartile, and declines monotonically by quartile. For example, the elasticity of electricity consumption with respect to electricity price is −0.681 among households in the first income quartile, −0.673 among those in the second quartile, −0.663 among those in the third, and −0.645 among those in the fourth. An F test of the null that these elasticities are all identical rejects the null at the 1% level or better (F statistic = 15.96, p-value less than 0.0001).

5.3. Dynamic Models and Models with Investments

Turning to the partial adjustment model, we report results based on the Blundell-Bond estimation procedure in Table 11. Column (A)

shows that the short-run own price elasticity of electricity consumption is −0.736, and the long-run one is −0.814, while the short-run cross-price elasticity (with respect to gas) is 0.265, and the long-run one is 0.293. For gas consumption, shown in column (C), the short-run own price elasticity is −0.572 and the long-run one is −0.647. The price of electricity is not significant in the gas equations. These equations include controls for the heating and cooling system, and we interpret them to imply adjustment when the current heating and cooling technology is considered irreversible.

In specifications (B) and (D) for electricity and gas, respectively, we exclude heating, cooling, and appliance dummies from the regression and interpret the result to apply when the choice of heating and cooling technology is reversible. It has been argued that durable goods and heating and cooling equipment are variable in the long-run, hence these specifications should result in a more pronounced response to energy prices. In fact, we do find slightly elevated price elasticities, but the differences are minor, on the order of 2% for electricity regressions, and 6% for gas regressions.

6. Discussion and Conclusions

The price and income elasticities of residential energy demand are important inputs into assessments of the effects of energy policies, demand forecasts, and greenhouse gas (GHG) emissions and impacts models. Existing estimates based on household-level energy consumption are based on either old data, or on recent, abrupt changes in prices due to supply conditions in geographically limited areas, and so it is unclear whether they are appropriate nationwide.

To address these external validity limitations, we assembled a mixed panel/multi-year cross-sectional dataset of households in the 50 largest metropolitan areas in the United States as of 2008. Our dataset documents utility bills, heating and cooling systems, appliances, and dwelling and household characteristics for over 69,000 dwellings (over 74,000 households) in the American Housing Survey from 1997 to 2007, for a total of over 98,000 observations. We merged these data with utility prices, and heating and cooling degree-days at the metro area level. To our knowledge, this is the most comprehensive set of data for examining household residential energy usage at the national level, containing the broadest geographical coverage, and with the longest longitudinal component (max $T=6$).

We estimate demand functions for electricity and gas. We control for unobserved heterogeneity in three alternate ways: (i) city-specific fixed effects exploit the variation in prices, dwelling characteristics, and state and local policies between observations, while (ii) dwelling-specific and (iii) dwelling-household effects rely on variation of prices, weather, and other local characteristics over time.

We find strong household response to energy prices, both in the short and long term. From the static models, we get estimates of the own price elasticity of electricity demand in the −0.860 to −0.667 range, while the own price elasticity of gas demand is −0.693 to −0.566. The dynamic models produce similar estimates, with short-

run (long-run) own-price elasticity of demand of −0.736 (−0.814) for electricity and −0.572 (−0.647) for gas.

Our relatively high price elasticity of demand is in sharp contrast with much of the literature on residential energy consumption in the United States, and with the figures used in current government agency practice. In its Annual Energy Outlook, for example, the Energy Information Agency (EIA) historically employed a short-term price elasticity of −0.15 for non-electric energy. In their 2010 report, EIA adopts an electric elasticity of −0.30 in anticipation of improved consumer awareness resulting from recent smart grid projects.[26]

By contrast, our estimate of the income elasticity is low, and only when we remove dwelling characteristics from the right-hand side of the regression equations does it reach 0.05. This figure is consistent with its counterparts in Rehdanz (2007) and Meier and Rehdanz (2010), who examine residential space heating *expenditures* in Germany and the U.K., respectively, using household-level data, but much lower than the income elasticity of energy demand (from all sources and sectors) typically used in many integrated assessment models (see Webster et al., 2008).

Taken together, our findings suggest that when prices increase households tend to substitute other inputs for energy and choose less energy-intensive appliances (or homes), and that as incomes rise, households tend to exhibit preferences for less energy-intensive appliances and homes (Webster et al., 2008). We leave it to future research to explore *which* energy efficiency investments, changes the stock of appliances, or conservation practices people undertake in response to price changes.

[26] The text refers specifically to smart grid projects funded under the American Recovery and Reinvestment Act of 2009 http://www.eia.doe.gov/oiaf/aeo/assumption/residential.html and EIA (2010).

ABSTRACT

We study the dynamic behaviour of household electricity consumption on the basis of four large independent surveys conducted in the province of Québec from 1989 to 2002. The latter region displays some rather unique features such as the very extensive use of electricity for space heating in a cold climate and the wide range of energy sources used to meet space heating requirements. We adopt Deaton (1985) approach to create 25 cohorts of households that form a pseudo-panel. The cohorts have on average 131 households. The model error terms allow for group heteroskedasticity and serial correlation. Short-run and long-run own and cross-price elasticities are statistically significant. Electricity and natural gas are estimated to be substitutes while electricity and fuel oil are complements, as it may occur in the Quebec context. The estimate of the income elasticity is not significant. Comparisons with related studies are provided.

1. Introduction

There is an ever-lasting interest in the economic analysis of energy demand and it is mainly due to societal concerns with respect to the environment, energy security, and energy price impacts on low income households and on industries. The foremost objective of all econometric studies dealing with energy demand is to shed some light on key parameters such as price and income elasticities and the adjustment process. This type of information is particularly useful in energy demand forecasting and

in the analysis of energy efficiency programs.[1] In this paper, we deal only with the residential sector. Dahl (1993) and Madlener (1996) provide surveys of econometric models of residential energy demand that rely on data generated over the 1970–1990 period. Dahl (1993) notes that price and income elasticity estimates vary significantly from one study to the next. The same conclusion can be reached if we consider more recent works: Poyer and Williams (1993), Hsing (1994), Maddala et al. (1997), Poyer et al. (1997), Silk and Joutz (1997), Garcia-Cerrutti (2000), Kamerschen and Porter (2004), Dergiades and Tsoulfifis (2008) and Borenstein (2009). The variability of parameters estimates is a reflection of the type of data used to estimate energy demand models, i.e. time series, cross-sections or panels, the sample period, and the extent of geographic aggregation, i.e. counties, states or countries. Model specification and estimation methods contribute also to the wide range of parameter estimates.

The multiplicity of approaches adopted to study energy demand is partly a consequence of the nature of available data. Aggregate time series have desirable features such as reliability and coverage; however they are subject to a major shortcoming with respect to the capacity to bridge a link between energy use and the major complementary appliances required to produce the services desired by users. The seminal work of Dubin and McFadden (1984) has drawn the attention to the estimation biases that may result from neglecting the simultaneous nature of the decisions to acquire a particular space heating system and to use it. Estimation of models as suggested by Dubin and McFadden requires cross-section data that can be very rich in terms of reported socioeconomic variables, however such cross-section data are not free from defects. Two shortcomings are particularly troublesome: one is the lack of energy price variability between consumers who live in the same service territory of a distribution utility and who face more or less the same energy prices by sources, i.e. electricity, natural gas and oil products. The other shortcoming is related to the dynamic nature of the relationship between energy use and the stock of complementary appliances. A single cross-section encompasses users who are at different stages of this evolving process. It is usually assumed that cross-section data portray users who are close to their long-run equilibrium; hence price and income elasticity estimates receive a long-run interpretation in such a context. However the dynamic nature of the adjustment process indicates that reality may not support this assumption in the case of electricity demand.

A way to address this last difficulty is to make use of panel data. However because of the high cost and the attrition that reduces the information obtained from panel samples, this type of statistical information is seldom available; rather what we have at our disposal in a few instances is a set of independent cross-sections that are collected at regular intervals. Following the path-breaking work of Deaton (1985), in this paper we build pseudo-panel data out of four independent cross-sections that come from large residential customer surveys conducted by Hydro-Québec, the electric utility that provides service to most users in the province of Québec. The observation units of pseudo-panel are cohort means. A cohort is a set of households that are grouped together according to specific membership criteria that remain the same for all surveys; the intent is to form a fairly homogeneous group. As it will be seen later on, a pseudo-panel provides a way to address the two aforementioned shortcomings of single cross-sections, i.e. lack of energy price variability and absence of information on the dynamic adjustment process. However aggregation into cohorts causes some information losses and there are trade-offs to be made along key dimensions such as number of households per cohort, number of cohorts, and homogeneity of households within cohorts.

To the best of our knowledge, this is the first application of pseudo-panel techniques in the context of household electricity demand. Furthermore the province of Québec has some distinctive characteristics with respect to household electricity consumption due to the extensive use of electricity for residential space heating in a rather cold climate and the diversity of energy sources that are used for this purpose.

The presentation proceeds as follows: in Section 2, we provide a brief introduction to pseudo-panel models; in Section 3, we specify the cohort electricity demand model and discuss some features of the data set; in Section 4, we describe the estimation method and the results. We also provide

[1] Several governments have introduced or are contemplating using programs or price incentives to curtail energy demand in light of the concerns with respect to global warning caused by greenhouse gas emissions. The impacts of such initiatives depend in part on price elasticities.

comparisons with electricity price and income elasticity estimates which were obtained in previous studies. Section 5 formulates some concluding comments.

Here is a summary of the main findings: the price variables of all the energy sources have statistically significant coefficients at the 1% level and electricity and oil products are complements while electricity and natural gas are substitutes. The income elasticity estimate is not statistically significant. The coefficient estimate of lagged electricity consumption is 0.62; this indicates a fairly slow adjustment process and it induces a large discrepancy between short-run and long-run elasticity estimates. We find that weather variables are not significant factors that influence electricity demand.

2. A brief introduction to pseudo-panel models

Panel data are composed of observations on the same units at different periods and they provide a rich set of information to analyze dynamic and static aspects of economic behaviour.[2] Unfortunately, panel data are expensive and subject to attrition that is likely to increase as the number of periods gets larger. Attrition may introduce a selection bias. Series of independent cross-sections are more readily available. The question then is how to best use independent cross-sections when we do not have access to real panel data? Deaton (1985) proposed to use cohort means as observations.

A cohort is defined as a group of individuals who share a set of characteristics that stay constant from one survey to the next such as age, place of residence, marital status and so on. Cohort means can be organized as a panel and form what is known as a pseudo-panel. Since cohort means are based on a set of individuals and not on the whole population, they can be viewed as approximation of population means and consequently, they are subject to measurement errors.[3] Deaton addressed this problem by applying error-in-variables techniques. When the number of individuals in each cohort is sufficiently large, measurement errors can be ignored. Indeed, most authors ignore measurement errors in empirical applications.[4]

The use of pseudo-panel data does not necessarily imply that estimation results are inferior to those obtained from genuine panel data since the latter are subject to attrition. Pseudo-panels present no such problem since individuals are not the same from one period to the next. Hence, there is a trade-off between more precise information subject to attrition and more complete pseudo-panel data subject to measurement errors.[5]

As with standard panel data, fixed or random individual (cohort) effects must be taken into consideration when use is made of pseudo-panel data. Let us recall that when the regressors are not correlated with individual effects, fixed and random effect estimators are both consistent; however the later is more efficient than the former. If individual effects are correlated with one or more regressors, the random effect estimator is no more consistent, but the fixed effect estimator still is.

Once the type of effects to be included has been determined, it is necessary to select an appropriate estimation method. Several estimators have been suggested in the context of standard panels: within, between, instrumental variables (IV), generalized method of moments (GMM), and maximum likelihood (ML) estimator; they are applied also in the context of pseudo-panels. Here are some instances: Browning et al. (1985) estimate life-cycle models of family consumption and labor supply by using a within estimator; Dargay and Vythoulkas (1998) and Dargay (2002) analyze a dynamic model of household car demand in the United Kingdom and a fixed effect model is estimated by applying the ML method; Gardes and Loisy (1997) estimate demand elasticity based on minimum income relative to declared income and uses the within and the between transformation while correcting for heteroskedasticity that may occur due to the aggregation of households into cohorts.

In the papers published thus far, few authors have taken into consideration the presence of hereroskedasticity and serial correlation with pseudo-panel data. Using real panel data based on California counties, Garcia-Cerrutti (2000) applied generalized least-squares to correct

[2] See Blundell and Meghir (1990) and Baltagi (2005).

[3] Real panels are not free from measurement errors either.

[4] For instances, see Browning et al. (1985), Blundell et al. (1994) and Moffit (1993).

[5] There are estimation methods available to address issues associated with incomplete panels. See Baltagi (2005). However there is still a loss of information caused by attrition.

simultaneously for heteroskedasticity and serial correlation in a dynamic electricity demand model with random effects. In this paper, we extend his work to pseudo-panel data. However we do not borrow his random coefficient specification since we have only access to four cross-sections.

3. Model specification, cohort creation and related data issues

3.1. Model specification

Electricity is an intermediate good used with complementary appliances to produce the desired services. These complementary appliances are durable or semi-durable goods; their life cycles usually span more than one year and are submitted to adjustment costs. This is why there is an interest in the short-run and the long-run responses of energy users to changes of economic conditions. Panel data are particularly useful to study household behaviour conditional on appliance holdings. Such panel data are not available in the province of Québec. However independent cross-sections are produced on a regular basis.

We assume that individual household electricity demand can be represented by the following dynamic model:

$$y_{nt} = \alpha y_{nt-1} + X_{nt}\beta + \theta_n + \varepsilon_{nt} \quad n = 1, 2, \ldots, N_t \text{ and } t = 1, \ldots, T. \tag{1}$$

where y_{nt} is the electricity demand of household n at period t, y_{nt-1} is its lagged value, α is its associated coefficient, X_{nt} is a vector of exogenous explanatory variables, β is a vector of associated parameters, θ_n is an unobservable individual effect, ε_{nt} is an error term, N_t is the number of households in the sample at period t, and T is the number of periods. In repeated independent cross-sections, N_t is not necessarily the same from one period to the next, and the index n is also changing accordingly. Thus it would be more appropriate to write $n(t)$, but to simplify the notation, we keep the index n.

Individual effects are assumed to be fixed; this is a fairly common assumption in the context of pseudo-panels.[6] The price of electricity is of particular concern in econometric studies of electricity demand because the marginal price is the relevant explanatory variable; the latter is not readily available due to the application of tariff schedules.[7] As it will be explained later on, cohort members face the same marginal price in a given year in our sample. When we estimate a model of individual household electricity demand, it is required to take into account the choice of heating system. This gives a non-zero value to the expected error term conditional on the choice of heating system. In our case, this non-zero value is tied to the household and it is incorporated into the fixed effect; we assume that it stays constant for a given cohort from one survey to the next.

When we aggregate individuals into cohorts and compute the mean for each cohort, we get the following model:

$$\bar{y}_{ct} = \alpha \bar{y}_{ct-1} + \bar{X}_{ct}\beta + \bar{\theta}_c + \bar{\varepsilon}_{ct}, \quad c = 1, 2, \ldots, C \text{ and } t = 1, \ldots, T. \tag{2}$$

where $\bar{y}_{ct} = (1/n_c)\sum_{n \in I_c} y_{nt}$, $\bar{X}_{ct} = (1/n_c)\sum_{n \in I_c} y_{nt}, \bar{X}_{nt}$, $\bar{\varepsilon}_{ct} = (1/n_c)\sum_{n \in I_c} \varepsilon_{nt}$, $\bar{\theta}_c = (1/n_c)\sum_{n \in I_c} \theta_n$, I_c is the set of households in cohort c, n_c is the number of households in cohort c, and C is the total number of cohorts.[8] Note that $\bar{y}_{ct-1}$ is the average lagged consumption of cohort c which comes most likely from a different set of households that had the same characteristics at period $t-1$.

Several factors related to cohort size, cohort location, and the nature of regional economic activities can make the error term of model (2) to be heteroskedastic. It is also possible that there is serial correlation between the error terms of two different periods. Therefore, we assume that

$$\begin{aligned} \bar{\varepsilon}_{ct} &= \rho \bar{\varepsilon}_{ct-1} + \bar{u}_{ct}, \\ E(\bar{u}_{ct}) &= 0, \\ \text{and } E(\bar{u}_{ct}^2) &= \sigma_c^2. \end{aligned} \tag{3}$$

---

[6] Instances are Deaton (1985), Browning et al. (1985) and Moffit (1993).

[7] As shown by Reiss and White (2005), the non-linearity of the marginal price may introduce a selection bias.

[8] I_c and n_c are not the same from one survey to the next and it would be more appropriate to make them a function of t. This detail is not included to keep the notation simple.

ρ is the autocorrelation coefficient that is common to all cohorts and σ_c^2 is the variance that is specific to cohort *c*. In this model, the error terms are subject to group heteroskedasticity and autocorrelation at the same time. However, it is assumed that the error terms of different cohorts are not correlated.

3.2. Cohort creation and data related issues

Our data base comes from four large independent surveys conducted by Hydro-Québec, a government owned utility that distributes more than 95% of the electricity in the province of Québec. In 2009, it sold 62 TWh to 3 649 470 residential users and the average rate was 7.2 Can.¢/kWh.[9] The latter is one of the lowest rates in North America as it can be seen in Table 1 and it is due to the combination of hydroelectric power and public ownership. In 2009, Hydro-Québec had access to 44 192 MW and 91.0% was hydro. The low electricity rates have created conditions favourable to electricity use: in 2000, the average use per capita was 30 687 kWh in Québec, 18 040 kWh in Canada,[10] and 14 684 kWh in USA. Here are the shares of residences in the province of Québec by main energy sources used for space heating in 2002: electricity (68%), oil (17%), wood (9%) and natural gas (6%). Furthermore many residences rely on dual-energy space heating systems such as electricity and fuel oil or electricity and wood. Québec residential households are in the rather unique position to rely heavily on electricity for space heating in cold climate. Furthermore they use a diverse mix of energy sources, either alone or in combination. Hydro-Québec conducted two large mail residential surveys in 1989 and 1994, and some 50 000 questionnaires out of 100 000 were filled.[11] It conducted two smaller phone surveys in 1999 and 2002 and the later have about 10 000 observations each.[12] These surveys provide information on appliance holdings, house characteristics and some socio-economic variables of the households.

In each cross-section, we have chosen only single-family houses: detached, semi-detached or row houses with separate outside entrance. This leads to a more homogenous sample since apartments and trailers are deleted.[13] Because electricity use is larger in single-family houses, this ensures that most users pay at the margin the highest rate of a two-block tariff. Furthermore only houses that were built or converted to another energy source for space heating during the most recent five-year span in each survey are included. This restriction ensures that only households who made a recent decision with respect to a new heating system are included in the sample. This increases further the

[9] Total sales within the province and exports were 165.3 TWh and 23.4 TWh, respectively. See Hydro-Québec (2010).
[10] Including Québec.
[11] The voluntary response to a mail questionnaire may introduce some biases in parameter estimates. Households who are more concerned with energy and the environment are more likely to participate in such surveys. This may create a positive estimation bias in price elasticity and a negative one in income elasticity relative to the overall population.
[12] The response rates to the phone surveys are not known.
[13] However owners of single family houses are usually at the high end of the income distribution. This has implications for the income elasticity estimates.

homogeneity of the sample and focuses on users that are the most likely to respond to energy price changes. Here are the numbers of observations that are drawn from each survey: 2897 in 1989, 4849 in 1994, 3123 in 1999 and 2155 in 2002.

Cohorts must be constructed according to some well-defined rules. In practice, an arbitrage must be performed between the number of cohorts (C) and the number of individuals by cohort (n_c). When C is large, then n_c is small and cohorts means are inaccurate estimates of the true means of cohort population. Verbeek and Nijman (1992) show that n_c must be sufficiently large for the within estimator to be consistent.

The two criteria that we rely upon to identify cohort membership are the region of household residence and her house size. The province is divided into nine administrative regions that vary in terms of population density, economic activity, and weather. Households who live in the same region share some common characteristics and their behaviour concerning energy consumption is related to these region specific characteristics. It should be pointed out that natural gas distribution is not available in low population density areas and it is totally absent east of Québec City. Conversely fire wood is plentiful in rural areas and in small cities, but is not so readily available in large cities.

As the objective is to analyze household electricity demand, an important factor is house size. Houses are partitioned into three groups: small surface (less than 1000 square feet), medium surface (between 1000 and 2000 square feet) and large surface (more than 2000 square feet). Let us recall that more than 60% of electricity used by Québec households is related to water and space heating; both uses are definitely related to house size.

These two criteria (region and heating surface) yield a set of $9 \times 3 = 27$ potential cohorts. Table 2 shows the distribution of cohort sizes by survey. Some cohorts have few observations because the population of these cohorts is small to begin with. Indeed, some regions in the province of Québec have much lower population density than others and this is reflected in the surveys. Two cohorts are merged with another in a neighbouring region and we finally kept 25 cohorts. The average cohort size is 131 households. Cohort sizes are deemed to be large enough to neglect measurement errors of population means.

Hydro-Québec surveys provide information on household income and electricity consumption comes from meter readings. Electricity marginal price is the price of the last block of the two-block tariff. Natural gas price is the average regional residential rate that is specific to each consumer; the province of Québec can be divided into four areas in this respect: two fairly small western regions, the no service area, and the remaining area. Heating oil price is also the average price paid within each of the nine administrative areas. No information is available on fire wood prices. Finally heating and cooling degree days are measured by Environment Canada at the major city of the administrative region. Nominal values are converted to real ones by applying Quebec CPI index.

4. Estimation method and empirical results

Model (2) has the pervasive problem that the lagged dependent variable is correlated with the serially correlated error term. Moffit (1993) extends Deaton's (1985) approach to the estimation of a dynamic model based on independent cross-sections. He interprets the within estimator as an instrumental variables estimator and cohort dummy variables fulfil the role of instruments. Moffit suggests to replace the lagged dependent variable $\bar{y}_{nt-1}$ by its predicted value obtained from data available at time $t-1$.

Verbeek and Vella (2005) examine the estimator proposed by Moffit (1993) and shows that Moffit's estimator is not consistent unless exogenous variables are time invariant or do not have any autocorrelation. They suggest an alternative approach also based on instrumental variables. Their approach makes use of the within estimator with cohorts means. The within estimator together with the augmented instrumental variables is consistent. Consistency requires a large number of cohorts in order to reduce the estimator bias.[14] We also use the instrumental variables (IV) method.

[14] This bias also exists when the within estimator is applied to dynamic models using real panel data and it is even larger than the bias of the within estimator with pseudo-panel data.

S = small surface, M = medium surface, L = large surface, T = total (i.e. S + M + L).

We assume that $\bar{y}_{ct-1}$ depends on some other variables:

$$\bar{y}_{ct-1} = \bar{W}_{ct-1}a_1 + \bar{Z}_c a_2 + \bar{\nu}_{ct-1},$$

where $\bar{W}_{ct-1}$ is a vector of time variant variables,[15] $\bar{Z}_c$ a vector of time invariant variables that are the cohort fixed effects, a_1 and a_2 are vector of parameters, and $\bar{\nu}_{ct-1}$ is an error term that is assumed to be independent and identically distributed. After instrumenting $\bar{y}_{ct-1}$, we obtain a consistent estimator of ρ, denoted by $\hat{\rho}$.[16]

$$\hat{\rho} = \frac{\Sigma_{c=1}^{C}\Sigma_{t=2}^{T}\bar{e}_{ct}\bar{e}_{ct-1}}{\Sigma_{c=1}^{C}\Sigma_{t=1}^{T}\bar{e}_{ct}^{2}},$$

where $\bar{e}_{ct}$ is the IV estimation residual of (2). $\hat{\rho}$ is then used to carry out the Prais-Winsten transformation in the following way:

$$\bar{y}_{ct}^{*} = \sqrt{1-\hat{\rho}^2}\,\bar{y}_{ct} \text{ and } \bar{X}_{ct}^{*} = \sqrt{1-\hat{\rho}^2}\,\bar{X}_{ct} \quad \text{for } t = 1,$$

$$\bar{y}_{ct}^{*} = \bar{y}_{ct} - \hat{\rho}\bar{y}_{ct-1} \text{ and } \bar{X}_{ct}^{*} = \bar{X}_{ct} - \hat{\rho}\bar{X}_{ct-1} \text{ for } t = 2,\ldots,T.$$

The instrumental variables are transformed in a similar fashion to obtain $\bar{X}_{ct}^{**}$. The transformed data are used in a IV application to obtain consistent estimators of cohort variances:

$$\hat{\sigma}_c^2 = \frac{1}{T}\sum_{t=1}^{T}\bar{e}_{ct}^{*2}$$

where $\bar{e}_{ct}^{*} = \bar{y}_{ct}^{*} - \bar{X}_{ct}^{*}\hat{\beta}$and $\hat{\beta}$ is the estimator obtained by applying OLS to the transformed data.

Note that the cohort effects are included in the $\bar{X}_{ct}$ and β is redefined accordingly. The variance estimators are then used to obtain the feasible generalized least square estimator (FGLS):

$$\hat{\beta}_{\text{FGLS}} = \left[\sum_{t=1}^{T}\sum_{c=1}^{C}\frac{1}{\hat{\sigma}_c^2}\bar{X}_{ct}^{**'}\bar{X}_{ct}^{*}\right]^{-1}\left[\sum_{t=1}^{T}\sum_{c=1}^{C}\frac{1}{\hat{\sigma}_c^2}\bar{X}_{ct}^{**'}\bar{y}_{ct}^{*}\right].$$

The use of pseudo-panel data with fixed effects provides a mixture of a between estimator (cohort means) and a within estimator (cohort fixed effects). The estimation results appear in Table 3.

The lagged dependent variable and the three energy prices are statistically significant at the 1% level. Electricity and natural gas are substitutes while electricity and fuel oil are complements. Complementary of electricity and fuel oil may be related to the fairly widespread use of this type of dual energy for space heating in Québec.[17] The lagged dependent variable captures most of the lethargy present in electricity consumption that is greatly related to house type, heating system and location. This explains why most cohort dummies are also not significant. Only Manicouagan (MAN), a region in the northeast part of the province, has two significant positive effects. It is unexpected to find that heating degree days (hdd) are not statistically significant, a result that is contrary to what was observed in a time series model estimated by Arsenault et al. (1995) and in a single cross-section model estimated by Bernard et al. (1996). Here are the factors that may explain this result in the current context. First, the lagged dependent variable includes the effect of systematic weather differences across regions; second, the cohort dummy variables incorporate also the permanent regional weather differences[18] and finally wood has been left out of the model and wood is more readily available in the northern and colder regions. Wood is mostly used as a supplementary source of heat in conjunction with the main space heating system. Net income is statistically significant only at the 10% level. The weak income effect, which is in line with previous findings, is reduced further here since the sample includes only single-family houses that are occupied by wealthier households.

[15] The variables that vary with time and have been chosen to constitute $\bar{W}_{ct-1}$ are: heating degree days, cooling degree days and the marginal price of electricity.

[16] Regarding the first observation, we suppose that it depends on cohort fixed effects only.

[17] A specific weather related tariff encourages that kind of space heating system.

[18] It turns out that the only two significant dummy coefficients are associated with a northern region.

Cooling degree days (cdd) are statistically significant only at the 10% level and furthermore it has a negative sign. Very few houses in Québec have a space cooling system; hence no relationship is expected between cdd and electricity use. However a negative sign is a possibility in Québec since higher cooling degree days may be associated with higher temperature in shoulder months such as April, May, September and October when heating systems are operating. Under these circumstances, higher cdd may simply imply that less heating is required. The variance estimates (σ_c^2) are not shown; they display heterogeneity and they range from 0.15 to 6.57.

Table 4 presents the estimates of income, price and cross-price elasticities of Québec household electricity demand derived from the estimated model; the estimates of the variances are computed using the delta method. All the short-run price elasticities are statistically significant at the 1% level and so are the long-run elasticities, except for natural gas. The short-run income elasticity is significant at the 10% level, but the long-run one is not.

Table 4 provides also the elasticity estimates of the Québec residential electricity demand that were obtained in two previous studies. Building on Dubin and McFadden (1984), Bernard et al. (1996) estimate a joint discrete/continuous model of household heating system choice and electricity demand on the base of the 1989 cross-section sample that is also used in this study. Since no lagged dependent variable appears as explanatory variable and the dependent variable is conditioned on space and water heating system, their estimates receive a short-run interpretation. We can see that the major difference occurs with respect to the oil cross-price elasticity which is positive and much smaller in absolute value in Bernard et al. (1996). Bernard and Genest-Laplante (1995) estimate a

When available, standard-errors are in parenthesis.

model of Québec residential electricity demand using aggregate time series data from 1962 to 1990.[19] Two significant differences between the two studies are the sign reversals of the two cross-price elasticities and the larger gap between the short-run and the long-run elasticity estimates due to the higher value of the coefficient of the lagged dependent variable.

We now turn briefly to two other studies that present estimates of dynamic household electricity demand models and that make use of a model specification similar to model (2); in particular, the error terms are assumed to be heteroskedastic and serially correlated in the context of panels built from regional data. However both studies allow also for regional dependency of the error terms and different serial correlations by region. Using annual data on 44 California counties from 1983 to 1997, Garcia-Cerrutti (2000) obtains the following estimates of short-run (long-run) income, electricity price and natural gas cross-price elasticities: 0.15 (0.17), −0.17 (−0.19), −0.10 (−0.11).[20] Contrary to this study, he finds that electricity and natural gas are complements. Such a finding is unexpected. Using annual data for five Southern states during the 1981–1990 period, Hsing (1994) gets the following estimates of short-run (long-run) income, electricity price and natural gas cross-price elasticities: 0.40 (0.90), −0.24 (−0.54), and 0.14 (0.32).[21] In comparison to the results presented in this study, he obtains higher income elasticities and lower direct price elasticities; electricity and natural gas are estimated to be substitutes as expected and cross-price elasticity estimates are almost identical in the two studies. Although the model specification of the two USA studies is close to the model specification as in this paper, it should be pointed out that the data have been generated in fairly different contexts and this exemplifies the fact that household electricity demand elasticity estimates depend very much on the data generating process.

5. Conclusion

In this paper, we use four independent surveys on household electricity consumption conducted by Hydro-Québec to build a pseudo-panel of cohort means that is used to estimate a dynamic model of household electricity demand in the province of Québec. Our sample includes only households who inhabit single-family houses built in the last five years before the survey or single-family houses that got a new heating system over the same period. This is a fairly homogenous group of households who are most likely to respond to energy price changes. Furthermore, cohorts allow us to introduce dynamic effects that are difficult to capture in a single cross-section. We find that all price effects are highly statistically significant, that electricity and natural gas are substitutes and that electricity and fuel oil are complements. However the income effect is not significant. The voluntary responses to survey questionnaires and the inclusion of only single-family houses in the sample may explain why

[19] See also Arsenault et al. (1995).
[20] Garcia-Cerrutti (2000) estimates a random coefficient model and a constant coefficient model. We present only the results of the constant coefficient model since this is the specification used in this study. He finds that only the natural gas cross-price electricity is statistically significant at the 5% level.
[21] All parameters estimates are significant at the 1% level.

our price elasticity estimates are at the high end while income elasticity estimates are at the low end relative to other studies.

Our results illustrate the point that electricity demand elasticity estimates are quite specific to the data generating process such as region, time period, and level of aggregation. Hence care should be taken to transfer parameter estimates from one region to another as it is often done in the analysis of energy programs or the use of computable general equilibrium (CGE) models.

Estimation of income elasticities from cross-section data

PETER DAX

Lehrstuhl für Volkswirtschaftslehre I, Universität Augsburg, Memminger Straße 14, D-8900 Augsburg, West Germany

I. INTRODUCTION

The term 'income elasticity of demand' is a quantitative measure of the relative variation of an individual's (or group of individuals') demand for a certain commodity when his (their) income varies. This measure can be of great interest for many purposes, *inter alia* for applied economic policy:

— the government wants to estimate reactions in consumers' demand when it plans changes in the tax system;
— the government plans to subsidize certain subgroups of the population;
— the government is interested in forecasting long-term changes in the economic structure of the country etc.

Income elasticities can be calculated by estimating Engel curves or demand functions from time-series of consumption data or from cross-section data of household consumption. In the case of cross-section data, usually a certain point, e.g. the mean or the median, of the underlying income distribution is chosen to calculate the income elasticity of demand for a certain commodity. This paper tries to show the necessity and possible ways of integrating the whole income distribution into the calculations of income elasticities.

II. THEORETICAL CONSIDERATIONS

The income elasticity of commodity j of individual i is defined as

$$\varepsilon_j^i(\mathbf{p}, \omega^i) = \frac{\partial f_j^i(\mathbf{p}, \omega^i)}{f_j^i(\mathbf{p}, \omega^i)} \Big/ \frac{\partial \omega^i}{\omega^i}$$
$$= \frac{\partial f_j^i(\mathbf{p}, \omega^i)}{\partial \omega^i} \cdot \frac{\omega^i}{f_j^i(\mathbf{p}, \omega^i)} \qquad (1)$$

0003–6846/87 \$03.00 + .12

where $f_j^i(p, \omega^i)$ is i's demand function for j; ω^i his budget (income); and $\mathbf{p}$ the price vector. $\varepsilon_j^i(\mathbf{p}, \omega^i)$ shows the relative variation of individual i's demand for commodity j when his income varies.

But it is questionable if this concept can be applied in empirical work where one has household cross-section data and wants to estimate the income elasticity of a commodity of a *group* of households or the income elasticity of the market demand for a commodity.

It has been common practice to compute the value of the elasticity at a certain point of an estimated statistical Engel curve, for example the mean or the median[1] of the income distribution of the group of households, although it is well known that the elasticity values may vary widely along the Engel curve. Therefore, the computed value need not be a good representation for the income elasticity with respect to the *whole* group of households. It may happen that a commodity j is classified as a necessity because at the median income we compute that $0 \leqslant \varepsilon_j \leqslant 1$, but it is inferior for all higher incomes.

Moreover, the method of measuring the income elasticity at only one point of the underlying income distribution leaves aside all considerations about changes in the relative dispersion of the income distribution with varying incomes. These changes, however, are important for the change of the market demand for the commodity whose relative size should be expressed by the income elasticity.

Stone (1954, p. 265) has developed a formula for the income elasticity of market demand for commodity j. Let G be the group of all consumers. Then:

$$\varepsilon_j = \frac{1}{\sum_{i\in G} f_j^i} \cdot \sum_{i\in G} \left\{ f_j^i \left(\frac{\omega^i}{f_j^i} \cdot \frac{\partial f_j^i}{\partial \omega^i} \right) \cdot \left(\frac{\sum_{i\in G} \omega^i}{\omega^i} \cdot \frac{\partial \omega^i}{\partial \left(\sum_{i\in G} \omega^i \right)} \right) \right\} \tag{2}$$

In words, 'the market income elasticity is equal to the weighted average of the products of the individual income elasticities and the elasticities of individual incomes with respect to total income' (Stone, 1954, p. 265).

Let $\bar{F}_j = \bar{F}_j(\mathbf{p}, \omega^1, \omega^2, \ldots, \omega^n) = \frac{1}{\#G} \sum_{i\in G} f_j^i$ ((mean) market demand) and $\bar{\omega} = \frac{1}{\#G} \sum_{i\in G} \omega^i$ (mean income). #G denotes the cardinality of group G. The above formula can easily be simplified:

$$\begin{aligned}
\varepsilon_j &= \frac{1}{\#G \cdot \bar{F}_j} \cdot \sum_{i\in G} \frac{\partial f_j^i}{\partial \omega^i} \cdot \left(\sum_{i\in G} \omega^i \right) \cdot \frac{\partial \omega^i}{\partial \left(\sum_{i\in G} \omega^i \right)} \\
&= \frac{1}{\#G \cdot \bar{F}_j} \cdot \sum_{i\in G} \frac{\partial f_j^i}{\partial \omega^i} \cdot (\#G \cdot \bar{\omega}) \cdot \frac{\partial \omega^i}{\partial \left(\sum_{i\in G} \omega^i \right)} \\
&= \frac{\bar{\omega}}{\bar{F}_j} \sum_{i\in G} \frac{\partial f_j^i}{\partial \omega^i} \cdot \frac{\partial \omega^i}{\partial \left(\sum_{i\in G} \omega^i \right)}
\end{aligned} \tag{3}$$

[1]See among many others Prais and Houthakker (1955, p. 94).

which means that the market income elasticity for commodity j is a function of the sum of the slopes of the individual Engel curves which are weighted by the individual increments in income with respect to the total income of group G.

In general, the value of the elasticity is dependent on the distribution of the increase in total income over the group of households. There is just one exception: all individual Engel curves are linear and have the same slope, i.e. $\partial f_j^i/\partial\omega^i$ is a constant for all i. In all other cases, one has to specify a distribution key in terms of $\partial\omega^i/\partial\left(\sum_{i\in G}\omega^i\right)$ or $\left[\left(\sum_{i\in G}\omega^i\right)/\omega^i\right]\cdot\left[\partial\omega^i/\partial\left(\sum_{i\in G}\omega^i\right)\right]$, according to the formula of the income elasticity, for further investigations.

Hildenbrand (1983b) considers two cases.

Case A: The individual increments are the same for all households. This may, for example, be the appropriate specification if one is interested in the impacts of certain subsidies for subgroups of households.

The distribution key is in this case

$$\frac{\partial\omega^i}{\partial\left(\sum_{i\in G}\omega^i\right)}=\frac{1}{\#G} \tag{4}$$

or, equivalently

$$\frac{\partial\omega^i}{\partial\left(\sum_{i\in G}\omega^i\right)}\cdot\frac{\sum_{i\in G}\omega^i}{\omega^i}=\frac{1}{\#G}\frac{\sum_{i\in G}\omega^i}{\omega^i}=\frac{\bar{\omega}}{\omega^i} \tag{5}$$

The elasticity of individual income with respect to total income is in the case of equal absolute income increments given by the ratio of mean income to individual income. The income elasticity of market demand for commodity j can be written as

$$\varepsilon_j(A)=\sum_{i\in G}\frac{1}{\#G}\frac{\partial f_j^i((\mathbf{p},\omega^i)}{\partial\omega^i}\cdot\frac{\bar{\omega}}{\bar{F}_j}. \tag{6}$$

Case B: The individual increments in income are the same for all households relative to their income. This specification implies that the relative dispersion of the personal income distribution is constant over time.[2] Calculating income elasticities under this assumption could be appropriate if one needs the values for considerations on long-run economic policy.

[2]This assumption is empirically confirmed for example by Schnitzer (1974, p. 39f.) who reports on the stability of the personal income distribution in the USA in the period from 1947 to 1971. This also implies that Case A can only be valid in the short term.

The distribution key is specified as

$$\frac{\partial \omega^i}{\partial\left(\sum_{i \in G} \omega^i\right)} = \frac{\omega^i}{\sum_{i \in G} \omega^i} \tag{7}$$

or, equivalently, as

$$\frac{\partial \omega^i}{\partial\left(\sum_{i \in G} \omega^i\right)} \cdot \frac{\sum_{i \in G} \omega^i}{\omega^i} = 1. \tag{8}$$

In the case of equal relative income increments for all individuals (households), the elasticity of individual income with respect to total income equals unity. The income elasticity of market demand can be written as

$$\varepsilon_j(\mathrm{B}) = \sum_{i \in G} \frac{\omega^i}{\left(\sum_{i \in G} \omega^i\right)} \cdot \frac{\partial f_j^i(\mathbf{p}, \omega^i)}{\partial \omega^i} \cdot \frac{\bar{\omega}}{\bar{F}_j}$$

It should be noted that if all individual incomes are equal, $(\omega^i / \sum_{i \in G} \omega^i = 1/\#G)$ the two elasticity concepts are equivalent.

If the group of households can be considered as homogeneous, i.e. all households have identical preferences and hence a common demand function $f(\mathbf{p}, \omega)$,[3] and the income distribution of this group can be described by a density function $\rho(\omega)$, we can derive formulae which are more convenient for both empirical and theoretical purposes.

We define the market demand function for commodity j as $\bar{F}_j$ and the mean income $\bar{\omega}$ as

$$\bar{F}_j = \bar{F}_j(\mathbf{p}, \rho) = \int_0^\infty f_j(\mathbf{p}, \omega)\rho(\omega)\,\mathrm{d}\omega \tag{9}$$

and

$$\bar{\omega} = \int_0^\infty \omega\rho(\omega)\,\mathrm{d}\omega. \tag{10}$$

The income elasticity can then be written[4] as

$$\varepsilon_j(\mathrm{A}) = \int_0^\infty \frac{\partial f_j(\mathbf{p}, \omega)}{\partial \omega} \rho(\omega)\,\mathrm{d}\omega \cdot \frac{\bar{\omega}}{\bar{F}_j} \tag{11}$$

[3]In empirical work one can try to approximate homogeneity of a group of households by a narrow definition of this group with regard to observable characteristics of households (household size and composition, age, occupation etc.). For a detailed discussion see, for example, Prais and Houthakker (1955, pp. 88–93 and 125–64). For a theoretical concept see Hildenbrand (1985, p. 44).
[4]Proofs are given in Hildenbrand (1983b).

in case A and as

$$\varepsilon_j(\mathrm{B}) = \int_0^\infty \frac{\partial f_j(\mathbf{p}, \omega)}{\partial \omega} \rho(\omega) \omega \mathrm{d}\,\omega \cdot \frac{1}{\bar{F}_j} \tag{12}$$

in case B.

III. FUNCTIONAL SPECIFICATIONS

The empirical application of the above derived income elasticity concepts requires considerations about the functions which should be used for estimation purposes.

Engel curves with income as the only independent variable were chosen. It is obvious that the resulting income elasticities differ from those which stem from Engel curves where other independent variables, for example, family size, asset holding etc. are introduced additionally.[5]

There are quite a lot of properties which a 'good' Engel curve should have.[6] These properties stem from considerations on economic, statistical and practical questions in demand analysis, but, unfortunately, there is no general consent to the above properties in the literature. Therefore, there is no *a priori* reason to trust in and use one certain algebraic formulation of Engel curve only. It is well known that income elasticities for the same commodity and estimated for the same set of household budget data can differ widely when they are derived from different functional types of Engel curves.

To overcome these difficulties ten different functional forms were used. If the fitted curves with respect to a certain commodity are similar, this may serve as a hint on the structure of the *real* Engel curve. On the other hand, the procedure may be regarded as posing the question as to what extent the parametric approach, which means the acceptance of a functional form, is appropriate in demand analysis, seen in contrast to parameter-free procedures (see, for example, Hildenbrand, 1985, pp. 53 ff.).

The functions

The linear function (P1):

$$X_j = a_j + b_j \cdot \omega \tag{A}$$

where X_j denotes the expenditure for commodity j.
The quadratic function (P2):

$$X_j = a_j + b_j \cdot \omega + c_j \cdot \omega^2 \tag{B}$$

The cubic function (P3):

$$X_j = a_j + b_j \cdot \omega + c_j \cdot \omega^2 + d_j \cdot \omega^3 \tag{C}$$

[5]Then the income elasticities are in a certain sense just partial elasticities which are in the case of a positive correlation of income and additional variables lower than those computed here.
[6]See for example Schmucker (1962, pp. 415 ff.), Prais and Houthakker (1955, pp. 82 ff.) or Streissler, E. and M. (1966, p. 83 f.).

The Working function (WO)[7]:

$$X_j = a_j \cdot \omega + b_j \log(\omega) \cdot \omega \tag{D}$$

The Leser function (LE):[8]

$$X_j = a_j + b_j \cdot \omega + c_j \log(\omega) \cdot \omega \tag{E}$$

The hyperbolic function (HY):

$$X_j = a_j + b_j/\omega \tag{F}$$

The log-inverse function (LI):

$$\log(X_j) = a_j + b_j/\omega \Leftrightarrow X_j = 10^{a_j \ b_j/\omega} \tag{G}$$

The semi-logarithmic function (SL):

$$X_j = a_j + b_j \log(\omega) \tag{H}$$

The double-logarithmic function (DL):

$$\log(X_j) = a_j + b_j \log(\omega) \Leftrightarrow X_j = 10^{a_j} \cdot \omega^{b_j} \tag{I}$$

The Goreux-function (GO):[9]

$$\log(X_j) = a_j + b_j/\omega + c_j \log(\omega) \Leftrightarrow X_j = 10^{a_j + b_j/\omega} \cdot \omega^{c_j} \tag{J}$$

For the approximation of an empirical income (or expenditure) distribution the lognormal distribution is usually recommended and used.[10] With the help of some basic properties of the lognormal distribution one can easily derive the theoretical formulae of the income elasticities for the different elasticity concepts and the different Engel curve specifications given above.

Consider the variate X $(0 < x < \infty)$ such that $Y = \ln(X)$ where 'ln' denotes the natural logarithm. If Y is normally distributed with mean μ and variance $\sigma^2 (Y \sim N(\mu, \sigma^2))$, then $X \sim \Lambda(\mu, \sigma^2)$ denotes that X is lognormally distributed and its distribution is completely determined by the two parameters μ and σ^2. The mean $\bar{x}$, median $x_{0.5}$ and mode x_{mod} have the relative positions

$\bar{x} = e^{\mu + \frac{1}{2}\sigma^2}$;

$x_{0.5} = e^{\mu}$; and

$x_{\text{mod}} = e^{\mu - \sigma^2}$.

There exist moments of any order. The jth moment about the origin is given by

$$\lambda_j = \int_0^{\infty} x^j \, d\Lambda(x) = e^{j\mu + \frac{1}{2}j^2 \cdot \sigma^2} \tag{13}$$

[7]Let $\log(z)$ denote the logarithm of z to base 10.
[8]This Engel curve has been proposed by Leser (1963) as a 'logical generalisation' of the Working function.
[9]This function was introduced by Goreux (1960) who called it 'log-log-inverse'.
[10]See for example Prais and Houthakker (1955 p. 13), Thatcher (1976, p. 227 f.) or Hildenbrand (1983a, p. 1001). Also Lydall (1976, p. 17) points out that the 'standard distribution' of earnings is 'approximately lognormal'. For a detailed treatise on the properties of the lognormal distribution see, for example, Aitchison and Brown (1957).

For a homogeneous group of households whose income distribution can be described by the lognormal distribution, we get for example in the case of the hyperbolic function:

$$\varepsilon_j(\mathrm{A}) = \frac{-b_j \cdot \lambda_{-2} \cdot \lambda_1}{a_j + b_j \cdot \lambda_{-1}}$$

$$\varepsilon_j(\mathrm{B}) = \frac{-b_j \cdot \lambda_{-1}}{a_j + b_j \cdot \lambda_{-1}}$$

and

$$\varepsilon_j(\mathrm{C}) = \frac{-b_j/\omega}{a_j + b_j/\omega}$$

where $\varepsilon_j(\mathrm{C})$ denotes the normal elasticity concept ($\varepsilon = \partial f/\partial\omega \cdot (\omega/f)$) and ω is the point of the income distribution (usually the median) where the elasticity will be calculated.

This example already shows that the numerical values of the elasticities, computed for the same commodity and the same functional specification for the Engel curve, will in general differ between the three concepts. The formulae for the other functions, as well as the results of the Engel curve estimations, are given explicitly in Dax (1985).[11]

IV. EMPIRICAL RESULTS

The household data used for the empirical analysis were collected in 1980 for the *Family Expenditure Survey* (FES) in Great Britain (excluding Northern Ireland) which is run by the Social Survey Division of the Office of Population Censuses and Surveys, the Department of Employment and the Central Statistical Office.

On the whole there are data on 6944 households. The recording period for every household was 14 days. The following goods, which had a high recording rate, were chosen for the estimations of the income elasticities: bread, offal, butter, margarine, tea, coffee, beer, wine and newspapers.

It was decided to include the data from *all* households in the calculations so that estimates of *market* income elasticities would be obtained. Values of market income elasticities are, of course, more interesting than values of income elasticities of subgroups of households. The problems of using budget data from non-homogenized households are obvious, but it is an open question how one would aggregate income elasticities correctly from different household groups to get a *market* income elasticity value.[12]

The income distribution[13] of the sample was approximated by a three-parameter lognormal distribution which was fitted by using the method of moments. The threshold parameter, which

[11] The example of the hyperbolic function also shows the dependence of the results from the functional specification of the income distribution and the shape of this distribution.

[12] This would require theoretical and/or empirical evidence on the development of the relative income weights of the household subgroups.

[13] In the empirical work household income was substituted by total expenditures following earlier examples of empirical research. For a discussion on this point refer to Prais and Houthakker (1955, p. 80 f.) and Goreux (1960, pp. 4 ff.). Nevertheless, the term 'income' is used throughout the paper.

defines a lower bound to the range of income values, is 5000 pence/week; λ_1, the first moment of the distribution, amounts to 110 603 pence/week. For the calculation of the elasticities $\varepsilon_j(C)$ the median of the distribution (89 886 pence/week) was used.

Tables 1 to 3 give the values of the income elasticities for the different commodities with respect to the different functional types of Engel curves and with respect to the different concepts of income elasticity. The values were calculated on the basis of estimated Engel curves. For the concepts A and B an integration procedure was run to derive, first, the corresponding market demand for the commodity and the functional specification of the Engel curve and then, in a second step, the elasticity value itself.

These integrations included, of course, the density function of the fitted lognormal income distribution. Values marked with an asterisk in Tables 1 and 2 stem from calculations where the underlying Engel curve was negative over a part of the empirically relevant range of the income distribution. Whereas usually the integrations were made over the range 5481 pence/week up to 1 318 617 pence/week, in the other case just over that range of incomes where the Engel curves were nonnegative was integrated.

A well known empirical result which shows up here once more is that the specific functional form of Engel curve has a strong influence on the value of the income elasticity of a commodity. In Table 3 it is found, for example, that the income elasticity of bread in the case of concept C, $\varepsilon_{\text{bread}}$ (C), ranges from 0.215 for the hyperbolic function to 0.554 for the Working function. Unless there are sound statistical reasons for using a specific function for these calculations explicitly which, however, did not show up in the present analysis, somebody who needs the exact numerical value of an elasticity may have severe problems.

More important for the present purposes, however, are the differences in the elasticity values for the same function with respect to the different elasticity concepts. The values of the hyperbolic function in the case of bread are 0.539, 0.265, 0.215; taking all three concepts and all functional forms the values range from 0.215 to 0.664. The situation is similar for all other commodities and even more extreme examples can easily be found. This clearly shows that the usual method of computing the income elasticity at only one point of the Engel curve may give misleading results.

There does not even seem to be a kind of *ordinal* structure in the elasticity values given in Tables 1 to 3.

(1) A specific functional form of Engel curve does not yield high or low values in *all* three concepts. For example: the log-inverse function on average shows the highest elasticity values in concept A, but only moderate values in concepts B and C; the cubic function which gives low values in concept A shows high values in concept C. This means that it is not possible to find a common ranking for the different functional forms with respect to the values they yield. The same phenomenon can be found for the functions with respect to the commodities: the Working function always yields the highest elasticity values for the 'necessary' goods – bread, offal, tea, margarine – but very low values for the 'luxury' goods – wine and beer – compared to the other functional forms.

(2) Can anything be said about the relations of the different concepts? One would be glad if one knew, for example, that concept X always yields higher elasticity values than concept Y.

To deal with this question it is helpful, first, to develop the explicit formulae for the income elasticities with respect to the different concepts and the different functional forms.

It then shows that concepts A and B are equivalent for the linear function and concepts B and C for the double-logarithmic function. Concepts A and B always differ (with the exception of the case of the linear function) in the numerators of the formulae. Concept A gives products $\lambda_i \cdot \lambda_1$ of moments, whereas Concept B gives the moment λ_{i+1}. Using the properties of the underlying income distribution, one can compare the expressions for concepts A, B and C for arbitrary parameter constellations.

In the empirical calculations $\varepsilon_j(A)$ is always greater than $\varepsilon_j(B)$ except in the case of the linear function, of course, and in the case of the commodity 'wine' for the Working and the double-logarithmic function. The relative difference of the values diminishes as the values rise.

For the hyperbolic and the semi-logarithmic function, the results always show the relation $\varepsilon_j(A) > \varepsilon_j(B) > \varepsilon_j(C)$. For the other functions it is usually found that $\varepsilon_j(A) > \varepsilon_j(C) > \varepsilon_j(B)$ except in the case of wine where $\varepsilon_j(C)$ may yield the highest values.

(3) One could, perhaps, be content to have at least a ranking of the elasticity values for the different commodities, so that statements as 'the income elasticity of good *j* is higher than that of good *i*' could be made. But even this is not possible. The relation may change from one function to the other. Moreover, this relation may change also for the same function when one compares the results of two different concepts. Example: the Goreux function shows the following ranking of elasticity values for concept A: $\varepsilon_{\text{bread}} > \varepsilon_{\text{butter}} > \varepsilon_{\text{margarine}} > \varepsilon_{\text{newspapers}} > \varepsilon_{\text{offal}}$, but for concepts B and C: $\varepsilon_{\text{butter}} > \varepsilon_{\text{newspapers}} > \varepsilon_{\text{bread}} > \varepsilon_{\text{offal}} > \varepsilon_{\text{margarine}}$. The same phenomenon appears for other functional forms.

V. CONCLUSION

In this paper we have repeated theoretical work on the integration of the income distribution of households into the estimation and calculation of *market* income elasticities. The theoretical considerations already show the necessity of this approach. The empirical calculations, which approximate the theoretical work as far as possible, yield results which underline this necessity.

But, the results also show two basic problems in the empirical application of the theoretical concept:

(1) It is absolutely necessary to have an *a priori* hypothesis on the change of the relative dispersion of the income distribution.

(2) The well known fact that different functional specifications of the underlying Engel curve may lead to quite different values of the elasticity. One can just hope that statistical results of the estimations show a superiority of a specific function over the others.

ACKNOWLEDGEMENTS

This article is more or less extracted from a previous paper (Dax, 1985), which was written while the author worked at the University of Bonn, Sonderforschungsbereich 21.

A New Look at Residential Electricity Demand Using Household Expenditure Data

Harrison Fell, Shanjun Li, and Anthony Paul

Abstract

We estimate residential electricity demand for different regions of the country, assuming that consumers respond to average electricity prices. We circumvent the need for individual billing information by developing a novel generalized method of moments approach that allows us to estimate demand based on household electricity expenditure data from the Consumer Expenditure Survey, which does not have quantity and price information. We find that price elasticity estimates vary across the four census regions—the South at –1.02 is the most price-elastic region and the Northeast at –0.82 is the least—and are essentially equivalent across income quartiles. In general, these price elasticity estimates are considerably larger in magnitude than those found in other studies using household-level data that assume that consumers respond to marginal prices. We also apply our elasticity estimates in a U.S. climate policy simulation to determine how these elasticity estimates alter consumption and price outcomes compared to the more conservative elasticity estimates commonly used in policy analysis.

A New Look at Residential Electricity Demand Using Household Expenditure Data

Harrison Fell, Shanjun Li, and Anthony Paul*

I. Introduction

The recent focus of the U.S. Congress on federal energy policy, which could substantially alter electricity prices, has elevated the importance of characterizing electricity demand behavior. This is particularly true for the burgeoning literature on the incidence of such policies (e.g., Burtraw et al. 2009; Hassett et al. 2009; and Shammin and Bullard 2009). A key parameter in incidence analysis is the household-level price elasticity of demand for electricity. Studies on residential electricity demand have been conducted for many decades, but few of them are based on household data, are national in scope, and allow for regional price elasticity heterogeneity.[1] This paper offers a new technique to estimate residential electricity demand for different regions in the U.S. using household expenditure data, under the assumption that consumers respond to average prices.

Many of the residential electricity demand estimations that use nationwide data are based on panel data, aggregated at the state level (e.g., Houthakker 1980; Maddala et al. 1997; and Bernstein and Griffin 2005). These studies have the advantage of being able to provide regional elasticities, both long-run and short-run, across the nation. However, one should use caution when applying elasticity estimates from these aggregate studies to policy analysis at the household level, as is often done in incidence analyses of climate policy. As Dubin and McFadden (1984) point out, demand estimations using aggregate data may be subject to misspecification bias due to aggregation over electricity usage and price. For example, if the underlying electricity demand at the household level takes nonlinear form (e.g., log–log), demand elasticities estimated using aggregate data (e.g., at the state level) will not represent household-level demand behavior.

* Fell and Li are fellows, and Paul is the Center for Climate and Electricity Policy fellow, at Resources for the Future, Washington, DC. The authors thank Dallas Burtraw for comments and discussions about this work and Josh Blonz for his excellent research assistance. This work was partially funded by a grant from the Center for International Climate and Environmental Research – Norway.

[1] See Taylor (1975) and Bohi (1981) for surveys of early electricity demand studies and Espey and Espey (2004) for a more recent collection of residential electricity demand elasticity estimates.

Several studies employ household-level data (e.g., Barnes et al. 1981; Dubin and McFadden 1984; Herriges and King 1994; and Reiss and White 2005), but these studies are constrained to geographically narrow regions because there is no national data set of electricity rate structures or of household-specific billing information. Given regional household heterogeneity, it may be inappropriate to apply estimates from these area-specific studies to all areas of the country. On a more practical note, getting geographically specific rate structure data for the entire nation and appropriately matching it up to individual households or obtaining household billing information for large geographic areas of the country is quite difficult because of the diversity of rate structures across the country and the proprietary nature of individual billing information.[2]

More importantly, all of the aforementioned studies using household-level data are based on the assumption that households know their marginal rate schedules and optimize accordingly. Although assuming that households respond to marginal prices is theoretically consistent in a utility-maximizing framework, it may not be a realistic representation of consumer behavior in electricity markets. The first reason for this is that many electric utilities, like some other public utilities, offer multitariff pricing where the marginal price for a household depends on the household's consumption. Deciphering an electricity bill to determine the rate structure is often not straightforward, and usually the bill arrives after the period of consumption has concluded. Thus, in many instances consumers may not be aware of their actual rate structure or their marginal price. Second, it may be unrealistic to assume that consumers can monitor and control their consumption at any given point in time during a billing period. If this is the case, then even if consumers know the rate structure, it is difficult for them to optimize consumption based on the marginal price.

Given these attributes of residential electricity consumption, the assumption that consumers respond to marginal price would be unlikely to hold for the average consumer. Indeed, this has been supported by increasing empirical evidence. Using data from seven Ohio utilities with decreasing-block rate schedules, Shin (1985) finds evidence that consumers respond to average prices from the utility bill rather than marginal prices. Based on residential billing data from Southern California Edison, which implements increasing-block pricing, Borenstein

---

[2] For example, in Reiss and White (2005), a study using rate structure data from Southern California, electricity rates had to be matched up indirectly with individual household data. Applying such techniques nationwide would quickly become intractable.

(2009) finds no evidence of bunching around the points where the marginal price increases, contrary to what a model of perfectly informed and optimizing consumers would imply.[3] In addition, he shows that the average price is a better indicator of consumer demand response than the marginal price. A recent paper by Ito (2010) using household billing data from two utilities in Southern California obtains the same finding that consumers are more likely to respond to average prices than to marginal prices.

Our study contributes to the literature by addressing the need for nationwide elasticity estimates using household-level data, under the assumption that consumers respond to average prices. Because gathering detailed rate structure data at the national level is impractical, we develop an empirical strategy based on the generalized method of moments (GMM) that allows demand estimation based on publicly available data sets. The main source of data is the Bureau of Labor Statistics' Consumer Expenditure Survey (CEX), which are supplemented with state-level data from the Electric Power Monthly reports produced by the Energy Information Administration (EIA). Though the CEX provides only expenditure data, our empirical approach permits estimations of household-level demand functions without observing household electricity usage or price schedules.

Our results show considerable differences in price elasticities across census regions, with elasticities ranging from –0.82 to –1.02 in the baseline model. These estimates are noticeably larger than other residential demand estimates using household-level data. However, as we demonstrate below, this difference is most likely attributable to the assumption that households respond to average electricity prices as opposed to marginal prices. This result suggests that further research is warranted to understand the prices to which consumers really respond in electricity demand. In addition to price elasticity, we also find small income elasticities, as is common in the electricity demand literature.

The remainder of the paper is organized as follows. In section 2, we present our data. This is followed with a discussion of our empirical method and a Monte Carlo analysis to gauge the effectiveness of the empirical method in section 3. In section 4, we use a simple graphic example to illustrate potential differences that can emerge in demand estimations based on average- or marginal-price responsiveness. Section 5 presents the results of the demand

[3] If consumers were responding to marginal prices, then in a multipart tariff rate structure one would expect to see a concentration of households at consumption levels just below the cut-off points for the rate change. Instead, Borenstein (2009) finds a much smoother distribution of consumption.

estimation, and section 6 illustrates the significance of demand elasticity assumptions in a policy analysis context. In the final section we give concluding remarks.

II. Data

Two data sets on household-level electricity usage are national in scope and publicly available: CEX and EIA's Residential Energy Consumption Survey (RECS). The CEX collects data through quarterly interviews of about 7,500 households.[4] The survey asks respondents to provide detailed expenditure information, including monthly electricity expenditures, but does not address quantity or price information for electricity use. The RECS collects information on residential energy use from fewer than 5,000 households and is conducted about every five years. It provides both electricity consumption (quantity) and expenditure data. Both surveys collect data on housing characteristics, appliances holdings, and household demographics.

We use the CEX data for our analysis for the following reasons. First, the CEX data have a much larger sample, with approximately 90,000 observations (7,500 households for 12 months) each year compared to fewer than 5,000 annual observations from RECS. Second, as mentioned above, the expenditure data from the CEX are available at the month level, the decision period we use in the demand analysis, whereas the data from RECS are at the annual level.[5] Finally, the state information for households is available only for the four most populous states in RECS for the purpose of confidentiality. On the other hand, the CEX data provide location information at the state level for all households. Because they lack state location, use of the RECS data would prevent us from using state-level cost shifters as the instruments for electricity price in the demand analysis and would restrict our ability to get regional price elasticities.

Our empirical analysis is conducted using the CEX data from 2004 to 2006. To reduce sampling errors and avoid instances of no observations in some months, we keep only the states that have at least 2,500 total observations in the survey over the period 2004–2006. This elimination process gives us a final sample of observations spanning 22 different states. The average number of observations in a month for each state ranges from 38 to 537 with a mean of 140. As will be shown in the next section, some of the moment conditions used for estimation

[4] The survey program also conducts a diary survey, in which respondents record all expenditures. However, we only use data from the program's quarterly interview survey. For more information on how the survey is conducted and the data available through the survey see http://www.bls.gov/cex/.

[5] Though the interviews are conducted quarterly, they ask questions about month-specific expenditures.

match average monthly household electricity usage predicted by the model to observed data for each state. Table 1 lists the states used in our analysis and the total number of observations by census region.

Table 2 provides summary statistics for monthly household electricity expenditure, average electricity price, imputed average household usage, and other variables that are treated as demand covariates. Average monthly household electricity expenditure, derived from the CEX, is highest in the South region at an average of $143, whereas it is lowest in the Midwest region at an average of $96. The average electricity price is based on state-level EIA data from Electric Power Monthly (based on EIA Form 826), where it is computed as the total revenue of electricity suppliers divided by the total electricity supplied. The state average price is highest in the Northeast region and lowest in the Midwest region. Based on the EIA average prices and the CEX expenditure data, we impute the naïve electricity usage for each household, shown as the "Quantity" row in the table.[6] The households in the South region use the most, whereas those in the Northeast region use the least.

The other explanatory variables in the demand analysis include house demographics, housing characteristics, and electric appliance holdings from the CEX data. We also obtain monthly heating degree days (HDD) and cooling degree days (CDD) for each state from the National Oceanic and Atmospheric Administration. These two temperature variables are interacted with appliances in the demand equation.

Our empirical method shown below necessitates instrument variables for electricity price. These variables should shift price schedules but do not affect consumption directly. Although local distribution companies, the entities that typically sell electricity to households, have largely regulated price schedules, these schedules often allow for built-in adjustments based on fluctuations in electricity generation costs, especially fuel costs. In addition, utilities often obtain power supply through procurements in advance to meet a larger share of their service obligations. We therefore use, as cost shifters, lagged prices of natural gas and coal (quarterly and yearly moving averages), as well as states' electricity generation profiles and the interaction between generation profiles and generation fuel prices. Coal and natural gas prices come from

[6] We consider this a "naïve" electricity usage measure because dividing household-level expenditures by a state average price neglects the reality that average prices at the household level will depend on a household's usage. Thus, basing a demand estimation on these naïve usage and state average price measures will pose not only standard simultaneity issues, but also measurement error issues. These points are discussed in more detail below.

EIA. Because these price data are often missing at the state level, we use national-level prices. The electricity generation profile data, which give the percentage breakdown of total generation by fuel type in each state, are also available through EIA.[7] We use the lagged values of these variables because electric utilities often procure a large of portion of power to be distributed ahead of schedule. In addition, lagged cost shifters are more likely to be exogenous to current demand shocks.

Figure 1 plots monthly national prices for residential electricity, coal, and natural gas from 2003 to 2006. All three series are trending up, with natural gas prices the most volatile and coal prices the least. Table 3 provides summary statistics of generation fuel profile variables. Across the four census regions, natural gas accounts for the largest share of generation in the West region (36 percent) whereas coal is used most extensively in the Midwest (70 percent). Nuclear and hydropower have the largest share in the West (40 percent) and Northeast regions (39 percent).

III. Empirical Strategy

Utilities frequently use nonlinear price schedules in selling electricity. The nonlinearity could be due to an up-front fixed charge, such as a transmission charge, and/or block pricing. The assumption maintained in most of the literature on electricity demand since Taylor's (1975) survey is that consumers are perfectly informed about the price schedule and are able to perfectly optimize on the margin at every moment: consuming the amount where the marginal value of electricity is equal to the marginal price. Although this assumption is theoretically appealing, it is unlikely to hold in reality. First, it is costly for consumers to obtain their price schedules because they are often not explicitly shown on electricity bills and because electricity bills arrive after consumption choices are made. In addition, price schedules are subject to month-to-month changes. Second, as electricity is billed from month-to-month, the above assumptions require consumers to make perfect predictions about their demand shocks, like a heat wave that raises the value of air-conditioning, for the whole month at the beginning of each month.

---

[7] Data for coal prices were downloaded from http://www.eia.doe.gov/cneaf/electricity/page/ferc423.html, and natural gas prices were downloaded from http://tonto.eia.doe.gov/dnav/ng/ng_sum_lsum_a_epg0_peu_dmcf_m.htm. State-specific electricity generation mix data were downloaded from http://www.eia.doe.gov/cneaf/electricity/epa/epa_sprdshts.html.

In light of increasing empirical evidence that consumers are more likely to respond to average prices rather than marginal prices (e.g., Shin 1985; Borenstein 2009; and Ito 2010), the goal of this paper is to obtain demand estimates under the assumption that consumers respond to average prices. This is a departure from, and in our view an improvement upon, the conventional assumption that consumers respond to marginal prices. At the very least, it offers an alternative demand estimation to the marginal price-response literature.

Method

Our empirical framework is set up based on the CEX data. As discussed above, although CEX provides a national representative sample, it does not have information on electricity price and quantity. Rather, it reports monthly household expenditure on electricity. Some previous studies using CEX data, such as Branch (1993), have used monthly state average prices from EIA as the price variable and constructed the quantity variable by dividing expenditure by the state average price, as we did above for our naïve usage variable. Although this method appears to be straightforward, the estimates could be biased due to at least two sources: measurement error and simultaneity. Measurement error arises because the average price faced by a given household will depend on its quantity consumed and, thus, will not typically be the same as the state average price given by EIA.

To illustrate the simultaneity problem, one can assume that the underlying demand function takes a double-log form commonly used in the literature on electricity demand

$$\ln q_{ist} = \beta \ln p_{ist} + x_{ist}\gamma + e_{ist}, \tag{1}$$

where t is the month index, s the state index, and i the household index. q_{ist} is the quantity of electricity used by household i in state s and month t, and p_{ist} is the average price for that household in month t. Under nonlinear price schedules, the average price depends on the quantity—in other words, p_{ist} is a function of q_{ist}. The simultaneous determination of household electricity usage and the price for that level of usage underlies the traditional simultaneity problem. The vector x_{ist} contains other variables that affect electricity demand, such as household demographics, appliance holdings, and weather conditions. The final variable, e_{ist}, is the demand shock and is assumed to be normally distributed with mean zero and $\text{var}(e_{ist}) = \sigma_e^2$.

Without observing both p_{ist} and q_{ist}, one could apply the naïve method that uses state average price $\overline{p}_{st}$ and imputed quantity $\overline{q}_{ist} = \frac{c_{ist}}{\overline{p}_{st}}$, where c_{ist} is monthly household expenditure, in equation (1), and it would become

$$\begin{aligned}\ln \bar{q}_{ist} &= \beta \ln \bar{p}_{st} + x_{ist}\gamma + (\ln \bar{q}_{ist} - \ln q_{ist}) + \beta(\ln p_{ist} - \ln \bar{p}_{st}) + e_{ist} \\ &= \beta \ln \bar{p}_{st} + x_{ist}\gamma + [\ln(\frac{c_{ist}}{\bar{p}_{st}}) - \ln(\frac{c_{ist}}{p_{ist}})] + \beta(\ln p_{ist} - \ln \bar{p}_{st}) + e_{ist} \\ &= \beta \ln \bar{p}_{st} + x_{ist}\gamma + (1+\beta)(\ln p_{ist} - \ln \bar{p}_{st}) + e_{ist} \\ &= \beta \ln \bar{p}_{st} + x_{ist}\gamma + v_{ist},\end{aligned} \tag{2}$$

where v_{ist} is the composite error term. If one were to estimate (2) taking v_{ist} as the error term, the estimates of both β and γ would be biased for two reasons, as long as β is not equal to –1. First, because the error term v_{ist} includes the state average price variable $\bar{p}_{st}$, $\ln \bar{p}_{st}$ is endogenous. Second, because demand factors x_{ist} affect electricity usage q_{ist}, which in turn would determine the average price paid by the household p_{ist}, x_{ist} is also endogenous as a result of the inclusion of p_{ist} in the error term. Because of the large number of endogenous variables in the equation, it would be impractical to use instrumental variable methods. In addition, the *a priori* direction of bias from the ordinary least squares (OLS) estimate is unknown: both $\bar{p}_{st}$ and x_{ist} are correlated with the error term, and it is unclear what direction the partial correlation between $(\ln p_{ist} - \ln \bar{p}_{st})$ and the explanatory variable takes.

We develop a new empirical strategy using GMM to estimate the demand function with the expenditure data from CEX and some auxiliary data that do not rely on the naïve quantity variable imputed from state average prices. Because we do not observe q_{ist} and p_{ist}, we cannot take equation (1) directly to the data. Instead, we further specify the average-price schedule faced by the household as the following

$$\ln p_{ist} = \alpha_s \ln q_{ist} + z_{ist}\delta + \varepsilon_{ist} \tag{3}$$

where α_s is the state-specific slope for the price schedule, and z_{ist} is a vector of observed variables that shift the price schedule, such as cost shifters, month dummies, and state dummies. This specification allows both the intercept and the slope of the average-price schedule to vary across states. ε_{ist} is the approximation error and is assumed to be normally distributed with mean zero and variance $\text{var}(\varepsilon_{ist}) = \sigma_\varepsilon^2$.

Household electricity usage and average price are determined by the demand equation and the price schedule. Solving for q_{ist} and p_{ist} from (1) and (3), we get

$$\ln q_{ist} = x_{ist}\gamma / (1-\beta\alpha_s) + z_{ist}\delta\beta / (1-\beta\alpha_s) + (e_{ist} + \beta\varepsilon_{ist}) / (1-\beta\alpha_s) \tag{4}$$

$$\ln p_{ist} = x_{ist}\gamma\alpha_s / (1-\beta\alpha_s) + z_{ist}\delta / (1-\beta\alpha_s) + (\alpha_s e_{ist} + \varepsilon_{ist}) / (1-\beta\alpha_s) \tag{5}$$

Given that the total expenditure $c_{ist} = q_{ist} \times q_{ist}$, $\ln c_{ist} = \ln q_{ist} + \ln p_{ist}$. With this, equations (4) and (5) allow us to express the total expenditure in logarithm as the following

$$\begin{aligned} \ln c_{ist} &= x_{ist}\gamma(1+\alpha_s)/(1-\beta\alpha_s) + z_{ist}\delta(1+\beta)/(1-\beta\alpha_s) \\ &\quad + [(1+a_s)e_{ist} + (1+\beta)\varepsilon_{ist}]/(1-\beta\alpha_s) \end{aligned} \tag{6}$$

Because we have data on electricity expenditure, equation (6) provides us with the basis for the first set of moment conditions. We define the predicted value of the log expenditure as

$$\ln \hat{c}_{ist} = x_{ist}\gamma(1+\alpha_s)/(1-\beta\alpha_s) + z_{ist}\delta(1+\beta)/(1-\beta\alpha_s) \tag{7}$$

And the first set of moment conditions is given by

$$E_{i,s,t}([x_{ist} \quad z_{ist}]'(\ln c_{ist} - \ln \hat{c}_{ist})) = 0 \tag{8}$$

Recognizing that some variables, such as month dummies and state dummies, are common in both x_{ist} and z_{ist}, we write the moment conditions this way to save notation. In essence, these moment conditions match the predicted expenditures (in log) with the observed ones. The first set of moment conditions alone does not provide enough restrictions to identify the model parameters. This is intuitive: one cannot separately identify the demand and price functions with only data on expenditure.

Taking advantage of state average prices available from EIA, we construct the second set of moment conditions.[8] Based on the state-level average price, we compute the state-level average quantity of household electricity usage, denoted by $\bar{q}_{st}$. The second set of moment conditions match the average quantity $\bar{q}_{st}$ with the predictions from our model. From equation (4), the expected value of electricity usage for a household, $\hat{q}_{ist}$, is given by

$$\hat{q}_{ist} = E(q_{ist}) = \exp(x_{ist}\gamma/(1-\beta\alpha_s) + z_{ist}\delta\beta/(1-\beta\alpha_s) + 0.5(\sigma_e^2 + \beta^2\sigma_\varepsilon^2)/(1-\beta\alpha_s)^2) \tag{9}$$

where the last term in the parenthesis is half of the variance of the composite error term in equation (4).[9] We define $\hat{\hat{q}}_{st}$ as the average of $\hat{q}_{ist}$ for all households in state s and month t (i.e.,

---

[8] EIA's Electric Power Monthly report, available for download at http://www.eia.doe.gov/fuelelectric.html, gives monthly average electricity prices by state.

[9] Given that e_{ist} and ε_{ist} are independent normally distributed random variables, $\ln q_{ist}$ is normally distributed. This implies that q_{ist} is log-normally distributed. Equation (9) is thus the expected value of a log-normally distributed variable.

$\hat{\bar{q}}_{st} = \frac{1}{I}\sum_{i=1}^{I} E(q_{ist})$). Based on $E[q_{ist} - \hat{q}_{ist} \mid x_{ist}, z_{ist}] = 0$, the second set of moment conditions can be constructed as

$$E_{ist}([x_{ist} \quad z_{ist}]'(\bar{q}_{st} - \hat{\bar{q}}_{st})) = 0 \tag{10}$$

Although the number of moment conditions constructed so far is larger than the number of model parameters, the standard errors of the two errors terms, σ_e and σ_ε, cannot be separately identified, given that they both enter moment conditions only through the last term in equation (9). We add another set of moment conditions based on the variance of errors in predicting log expenditure. Following equation (6), we get

$$E_{ist}(\ln c_{ist} - \ln \hat{c}_{ist})^2 - [(1+a_s)^2\sigma_e^2 + (1+\beta)^2\sigma_\varepsilon^2]/(1-\beta\alpha_s)^2 = 0 \tag{11}$$

We stack the three sets of moment conditions and use an iterative GMM procedure to estimate all the model parameters. In obtaining the starting values for the GMM procedure, we first estimate equations (1) and (3) using two-stage least squares, where we take the state-level average prices as the price variable for all households in the corresponding state. We use the identity matrix as the initial weighting matrix and construct the efficient weighting matrix based on parameter estimates from the first iteration.

The underlying model of our analysis assumes that consumers respond to average price in their electricity usage decisions. The interaction between the household demand function and the average-price schedule determines monthly electricity usage and average price at the household level. In addition to the challenge of not observing either household quantity or price data directly, we also face the common simultaneity identification challenge in the empirical demand and supply analysis: quantity and price are determined simultaneously. To deal with the simultaneity problem, our procedure, cast in a system of two equations (i.e., equations (1) and (3)), essentially uses demand-side variables, such as household demographics and appliance holding, to serve as instruments for the quantity variable in the price equation (3), and uses cost shifters, such as shares of fuel types in electricity generation and their interactions with fuel cost, to serve as instruments for the price variable in the demand equation (1).

Notably, although the nature of the CEX gives us some longitudinal information, the relatively short time span analyzed and the lack of detailed product information does not give us sufficient information to estimate the relationship between electricity prices and appliance replacement. We therefore consider our estimates short-run demand estimates.

Monte Carlo Analysis

The empirical strategy outlined above aims to estimate the demand function for residential electricity at the household level for different regions of the country in the absence of household-level price and quantity data. It uses the expenditure data from CEX together with state average electricity prices in a GMM framework. Before showing the estimation results, we present a Monte Carlo analysis to illustrate the effectiveness of the empirical strategy.

The Monte Carlo analysis is based on four states, each of which has more than 2,500 households in the CEX in the Northeast Region (Massachusetts, New Jersey, New York, and Pennsylvania). We first generate price and quantity data for each household, using the demand and price equations (4) and (5) and based on a vector of household characteristics from CEX, cost shifters, and a given set of parameters. The household characteristics, a subset of those listed in Table 2, include household income, number of rooms in the house, and household size. The cost shifters, a subset of those listed in Table 3, include the share of electricity generated using natural gas during the past three months, the share of electricity from coal, and that from nuclear and hydropower. Based on these variables and parameters, we generate monthly expenditure data at the household level and monthly state average electricity price and quantity. We then use both OLS and the GMM approach discussed above to recover the parameters used to generate the data. The OLS approach uses equation (2), where state average electricity prices are used in place of household average prices and quantities are imputed using monthly expenditure divided by state average prices.

Table 4 compares the values of the parameters used to generate the data (the true parameters) to their estimates from OLS and GMM for the different average-price schedules. In all three cases, the GMM method is able to recover the true parameters in the demand equation, whereas the OLS method gives the biased estimates, especially for *log*(*price*), the key variable of interest. To save space, we do not report the results for the 17 dummy variables (4 state dummies, 2 year dummies, and 11 month dummies).

The first panel presents the results for the demand equation where the average-price schedules in all four states are assumed to be upward sloping, with slopes of 0.4, 0.3, 0.2, and 0.1, respectively. The true parameter for *log*(*price*) in the demand equation is –0.8. Whereas the OLS provides an estimate of –0.512 with a standard error of 0.096, the estimate from the GMM approach is –0.837 with a standard error of 0.088. In addition, the OLS estimate on *log*(*household size*) is also statistically different from its true value of 0.4, whereas the GMM estimate is not at any conventional significance level.

The second case is based on simulations where the average-price schedules in all four states are downward sloping, with slopes of –0.4, –0.3, –0.2, and –0.1, respectively. All other parameters are kept the same as in the first panel. The parameter estimates from OLS for the four demand variables shown in the table are all statistically different from their true values, whereas none of the GMM estimates are. The most striking bias from OLS is still in the parameter estimate for *log*(*price*). The estimate from OLS is –1.117 with a standard error of 0.059, compared with the true value of 0.8.

The third panel provides results for simulations that assume positive slopes for the average-price schedule in the first two states but negative slopes in the other two states. In this case, the OLS results are closer to the true values than in the previous cases. Nevertheless, the coefficient estimate on *log*(*price*) is still statistically different from the true parameter at the 10 percent significance level.

The key finding of the simulations is that the GMM approach is effectively able to recover the true parameters, whereas the OLS estimates could result in substantial bias. Although the bias for the coefficient estimate on *log*(*price*) has the same direction as the slopes of the average-price schedules in the first two cases, this finding may not be robust to the addition of more demand-side variables in the regression. As discussed above from equation (2), the direction of bias depends on the *partial* correlation between a particular variable (e.g., *log*(*price*)) and the error term.

IV. Price Elasticities: Average-Price vs. Marginal-Price Response

Assuming that consumers are marginal-price responders in empirical studies if they actually respond to average price could have important implications for price elasticity estimates. In the case of block pricing, a change in average price would imply a larger change in marginal price. Therefore, one would expect demand curves estimated based on average-price responsiveness to be more price elastic than those based on marginal-price responsiveness.

To illustrate the potential for differences in price elasticity estimates based on the two different assumptions, consider the following simple example presented graphically in Figure 2. To understand how the price elasticity is identified, assume that the market consists of three households, A, B, and C, where A and B are on the lower tier of the price schedule and C is on the higher tier. Assume that the quantity demanded, Q_i, is linear and fully determined by income, X_i, and price, P_i, such that $Q_i = \alpha X_i - \beta P_i$, i = (A, B, C). P_i is the price that consumers respond to and it could either be the marginal price or the average price. For concreteness, suppose we observe that ($Q_A = 3$, $X_A = 15$), ($Q_B = 4$, $X_B = 20$), ($Q_C = 6$, $X_C = 40$). We assume that there is no fixed cost, and because A and B pay the same marginal price, they also pay an identical average price, say $P_1 = 0.10$. Household C pays a marginal price on the higher portion of the two-part marginal pricing schedule, and it is assumed to be $P_2 = 0.15$.

We now show how to identify demand parameters under the assumption that consumers respond to marginal prices in their electricity usage decisions. Given that households A and B face the same price, the parameter α can be identified by dividing the difference in quantity consumed between households A and B by the difference in X. In this example, that leads to an estimate of $\alpha = (4 – 3)/(20 – 15) = 0.2$. The effect of a change in marginal price on demand can be determined by adjusting C's income level to that of B's. Given $\alpha = 0.2$, if B and C paid the same price for electricity, then C would consume four more units than B. Thus, if a hypothetical household, B', had the same income level as B but faced the same marginal price as C ($P_2 = 0.15$), it would consume four fewer units than C, resulting in two units of electricity. Connecting points X, corresponding to $P_2 = 0.15$ and $Q'_B = 2$, and Z, corresponding to $P_1 = 0.10$ and $Q_B = 4$, where both have the same income but different marginal prices, we obtain the demand curve for the case where consumers respond to marginal prices. The slope of the demand curve, D^{MP}, is $\beta = (4 – 2)/(0.1 – 0.15) = –40$. This implies a price elasticity, evaluated at Q_B, for the marginal-price demand curve of $\varepsilon^m = \beta/Q_B \times P_1 = –1$. This way of identifying the price elasticity underlies the identification strategy used by Reiss and White (2005), where consumers are assumed to respond to marginal prices.

To identify the demand curve for the case where consumers respond to average prices, note that if the cut-off quantity $Q^* = 4.5$, average prices paid by the three households are $\overline{P}_A = \overline{P}_B = 0.10$ and $\overline{P}_C = 0.1125$. Using the same identification strategy as described above, α would again be 0.2. Again, a hypothetical household, B', with the same income level as B but facing the same average price of 0.1125 as C, would therefore consume two units of electricity (four units less than C). Connecting points Y, corresponding to $P_2 = 0.1125$ and $Q'_B = 2$, and Z, where both have the same income but different *average* prices, we obtain the demand curve under the assumption of average-price response, D^{AP}. This results in a much flatter demand slope of $\beta = –160$ and price elasticity at Q_B of $\varepsilon^a = –4$.

This simple illustration shows that, for the same observations, estimating the demand function under the assumption of average-price responsiveness will result in much more elastic demand than that estimated under the assumption of marginal-price responsiveness.[10] The degree to which the price elasticities will differ is, of course, a function of the data used. Because we do not have individual rate structures for all individuals in our sample, we are not able to estimate the corresponding demand curves under the assumption of marginal-price responsiveness. However, using rate structure data for households served by Southern California Edison, Borenstein (2009) is able to estimate elasticities with respect to both marginal prices and average prices. He finds that the demand function specified over average prices results in an elasticity estimate at least double (in magnitude) that from the demand function specified over marginal prices.

V. Estimation Results

In this section, we first present estimation results for the baseline model, in which price elasticities are assumed to be invariant to income levels. We then present results for models relaxing this assumption. Note that the term *baseline* refers not the method of estimation, but to the set of variables and observations included in the model. The baseline and alternative models are estimated by the GMM procedure described above and by OLS.

Baseline Model

We estimate the empirical model outlined in the sections above separately for each of the four census regions—Midwest, Northeast, South, and West. We do this for two reasons. First, as a result of differences in weather conditions and appliance holdings, for example, demand parameters (e.g., on electricity price and month dummies) differ across regions. Estimation by region allows for region-specific demand parameters. Ideally, we would like to have even more regionally specific demand parameters by estimating the model state by state. However, state-level estimations are infeasible because there is not enough variation in instrumental variables for electricity prices (i.e., cost shifters) to identify the model. Second, the empirical method is data-intensive and computationally intensive because of the larger number of moment conditions and parameters. Estimating the model by region made the problem computationally tractable.

In the baseline model, we drop observations in the upper and lower 2.5 percentiles of electricity expenditure from each region to avoid the effects of outliers (e.g., college

[10] Note also that a similar example using a decreasing-block price schedule would yield the same result with respect to price elasticities as the increasing-block price schedule example described above.

dormitories), possible data entry errors, and households generating a large proportion of electricity by themselves (e.g., through solar panels). For example, the maximum monthly electricity expenditure is \$2,946 by a household with an annual income of \$157,720. Assuming constant monthly income implies the highly unlikely possibility that more than 22 percent of monthly income was spent on electricity. At the other extreme, we have 31 observations with a monthly expenditure of \$10. Among these observations, the household income ranges from \$4,071 to \$440,910 with a mean of \$61,229. We suspect that, if this is not due to data entry error, then some of the observations may come from households that have used self-generated electricity or subsidized electricity through a low-income assistance program. In addition, the use of a linear function to approximate a nonlinear average-price function may not work well at low or high values of consumption in the case of tiered pricing. As mentioned above, we also drop states with fewer than 2,500 observations from the sample to ensure a reasonably large number of observations in each state for each month, which is particularly important for the consistency of the second set of moment conditions. We perform robustness checks with respect to data censoring, and the results are provided below.

Table 5 presents parameter estimates for the baseline model by census region from OLS. The electricity demand also includes state dummies, year dummies, and month dummies, but the parameters associated with these variables were omitted for brevity. Due to the log–log specification used, the parameter on *log*(*price*) in the first row provides price elasticity estimates. The differences in price elasticities across the four regions are substantial and are challenging to explain. According to the OLS results, the West region is the most price elastic with an elasticity of –1.02, whereas the Northeast region is the least price elastic with an elasticity of –0.385. Income elasticities, on the other hand, are very similar across the regions, ranging from 0.061 in the Midwest to 0.072 in the West. Other demand parameters generally have intuitive signs. The appliances in the table, especially electric space heating, increase electricity demand significantly. In the Northeast region, having electric heating increases electricity demand by almost 31 percent at the mean level of HDD (4.55). As discussed above, the OLS estimates could suffer bias as a result of both simultaneity and measurement error issues, and the direction of bias is unknown *a priori*.

Table 6 presents estimation results from GMM. The first row presents price elasticity estimates and their standard errors. Comparing this with the OLS results, two differences are obvious. First, the estimates of price elasticities from GMM in all four regions are noticeably different from their OLS counterparts. The GMM estimates in the first three regions are at least double the OLS results, whereas the elasticity estimate for the West region changes less substantially from –1.02 to –0.88. Second, although significant differences in elasticities remain across regions in the GMM results, the differences are much smaller than those observed from OLS.

Based on the GMM results, the Northeast region is the least price elastic with an elasticity of –0.82, whereas the South region is the most price elastic with an elasticity of –1.02. This result is as expected. Electricity usage is a result of the flow of services from a household's electricity-using appliances. Therefore, a household's ability to respond to a change in electricity price will depend largely on the type and number of appliances for which usage can easily be adjusted. For example, using an end-use demand specification, Reiss and White (2005) show that electricity price changes have the largest demand effects among households with electric space heating and air conditioning, two appliances that often account for a large portion of total household consumption and have easy-to-vary usage. The South region has the highest share of electric space heating at 54 percent compared to only 10 percent in the Northeast. In addition, air conditioning ownership (both central and window air conditioning) is 99 percent in the South compared to only 80 percent in the Northeast region, as shown in Table 2. Altering the use of these appliances is a significant end-use margin on which households can adjust electricity usage. Thus, households with electric space heating and air conditioning are likely to have more price-elastic demands. In the Northeast and Midwest regions, home heating often plays a relatively more significant role than home cooling, but because many homes have natural gas heating, there is not as obvious an end use on which to alter electricity consumption.

The other noticeable feature of our price elasticity estimates is that we find demand to be roughly twice to three times more price elastic than do several other studies using household-level data (e.g., Barnes et al. 1981; Dubin and McFadden 1984; Herriges and King 1994; Reiss and White 2005). All of these studies are based on household-level data matched with actual rate schedules faced by households in specific geographic areas. As pointed out by Dubin and McFadden (1984), household-level data are preferred over aggregate data (e.g., aggregated at the state level) because it could avoid misspecification bias due to date aggregation over electricity usage and price. Using household data in 23 large U.S. metropolitan areas from 1972 to 1973 in the CEX, Barnes et al. (1981) obtain a price elasticity estimate of –0.55. Dubin and McFadden (1984) use a 1975 household survey and estimate a price elasticity of –0.26. Based on data from a controlled experiment in Wisconsin from 1984 to 1985, in which participants were subject to five different rate schedules, Herriges and King (1994) obtain a price elasticity of –0.02 for the summer season and –0.04 for the winter. Reiss and White (2005) use the California subsample of the 1993 and 1997 survey waves of RECS and obtain a price elasticity of –0.39.

The first difference between our study and those four studies is that we are using representative national-level data rather than data from a particular region. More importantly, those studies assume that households respond to marginal prices, whereas we assume that households respond to average prices. As illustrated in the previous section, this difference can lead to drastically different estimated price elasticities. The question of which price consumers respond to in electricity demand is beyond the scope of this study but, as previously mentioned, mounting evidence suggests that consumers respond to average prices, and that result stands to reason. Nevertheless, the importance of this question is underscored by the significant difference between our results and those from studies assuming marginal-price responsiveness.

The second row of Table 6 shows estimates of income elasticities across four regions from the GMM procedure. Differences also exist between these estimates and those from OLS, although the differences are not as large as those in the price elasticity estimates. For example, the largest disparity in estimates comes from the income elasticity estimate for the Midwest region, which is 0.061 from OLS and 0.109 from GMM. The South region has the smallest income elasticity of 0.051 based on GMM results. Unlike the price elasticity estimates, these small income elasticity estimates are within the range found in previous studies. Barnes et al. (1981) obtain an income elasticity estimate of 0.20, whereas Dubin and McFadden (1984) get an estimate of 0.02. Herriges and King (1994) provide an estimate of 0.45, whereas Reiss and White (2005) find no statistically significant income effect.

The remaining parameter estimates in Table 6 correspond to housing characteristics, demographic information, and appliance holding variables. The characteristics of the housing unit we control for include a variable for house size (# of rooms), variables on housing unit age, a dummy if the housing unit is owned (Owned House), and a dummy if the unit is a single-family dwelling (Single House). As expected, we find that electricity consumption increases with increasing house size in all regions. Interpretation of the remaining housing characteristics is not as straightforward.

With respect to the house age characteristics, we control for the age of the house (House Age), a dummy equaling one if the house was built before 1970 (D_{70}), and the interaction between these variables (D_{70}*House Age).[11] The positive parameter estimates on House Age in all regions except the Midwest imply that electricity usage increases with house age for those built after 1970. The interaction between D_{70} and House Age allows the age effect on electricity usage to be different for houses built before 1970 from those built after. Except for the Midwest region, the parameter estimates on the interaction term are all negative, suggesting that the age effect in these regions is smaller for pre-1970 houses than for post-1970 houses. This result could be because much older houses have been renovated and, consequently, have been made more energy efficient.

For the house ownership dummy variable, we find a positive and statistically significant effect of homeownership on electricity consumption. This may seem surprising at first glance. One would expect that homeowners would be more likely to purchase an energy-efficient capital stock because they will accrue the benefits from such stock over a longer period, leading to conditionally lower electricity consumption than renters. Indeed, in a recent study using RECS data, Davis (2010) finds that renters are more likely to have fewer Energy Star appliances than homeowners. However, the ownership of energy-efficient appliances may be counteracted by more time spent in the housing unit and/or a greater frequency of appliance usage. Though we have no specific data on these issues, some evidence from our data appears to be consistent with the notion that homeowners are at home more often and/or use appliances more frequently. For example, if more senior individuals are more likely to spend time in the home than younger individuals, given our positive homeownership effect, we would expect that seniors would occupy a greater percentage of owned homes than rented homes. Indeed, our data show that 40 percent of homeowners, but only 18 percent of renters, are over the age of 64. Similarly, one might also expect that having more children may lead to more hours spent in the home and greater use of energy-intensive appliances such as washers and dryers. Again, our data show that the average number of children under the age of 18 in owned homes for individuals under the age of 64 is 0.9, compared to 0.8 for renters under the age of 64.

With respect to appliance holdings, we find that most of the parameter estimates for appliance holding have statistically significant values and intuitive signs. For instance, our

[11] We use 1970 as a somewhat arbitrary cut-off point between "older" construction and "newer" construction. We have also tried cut-off years above and below 1970 and these do not substantially change our results. Additionally, if this was a totally arbitrary and meaningless cut-off, we would expect to find a statistically insignificant parameter estimate on D_{70}.

demand estimation shows that electricity demand increases when households have electric space heating, air conditioners (window units or central air conditioning), a swimming pool, or an electric cooking appliance. Except for the interaction term between CDD and Swimming Pool in the South region, all of the interaction terms between appliance and weather variables (CDD and HDD) have positive signs, as intuition would suggest.

Although our paper is focused on electricity demand, the identification relies on using cost shifters as instruments, a common strategy in demand estimation. The baseline model uses 10 instruments: quarterly and yearly moving average lagged share of electricity generation from coal, the share from natural gas, that from hydro and nuclear, the interaction between the share from coal with lagged coal price, and the interaction between the share from natural gas with lagged natural gas price. The estimation results show that most of the cost shifters are statistically significant. The yearly moving average variables generally have a larger effect than do the quarterly variables, indicating that electricity prices are often affected by supply conditions even one year prior to production. We conduct a robustness check on the use of instruments in the next section, together with other sensitivity analyses.

Additional Specifications

In considering the distributional impacts of policies that affect electricity prices, like federal energy or climate policy, policymakers are concerned not only with geographical distributions of cost, but also with distributional effects across income groups. That is, households with different income levels may be affected differently by policies that affect electricity price. Our first alternative specification is therefore to examine if there is heterogeneity in price sensitivity across income groups. To that end, we interact *log*(*price*) with income interval dummies that capture four levels of household income: below $25,000, between $25,000 and $45,000, between $45,000 and $80,000, and above 80,000.

Table 7 shows parameter estimates for the four interaction terms between price and income dummies. Parameter estimates for the other variables are very close to those reported in the previous two tables and are omitted from this table. Panel 1 of Table 7 shows the OLS results, and Panel 2 shows the GMM results. Both panels show no economically significant differences in price elasticities across income categories. There could be multiple reasons why we fail to detect significant differences in price elasticities across income groups. First, although lower income groups respond to higher prices by using electricity-consuming products less, higher income groups may respond to higher prices by buying more energy-efficient products but maintaining product use levels. Second, lower-income households may cut back their usage of many commonly found electricity-intensive appliances (e.g., air conditioning) more than higher-income households, but high-income households may also have more nonessential electricity-consuming products (not controlled in the estimation) that can easily be used less when electricity prices are high. If this is the case, elasticity estimates should be relatively constant across income classes.

As stated above, the data exclusion made on the presented results was to remove households with the top and bottom 2.5 percent of electricity expenditure and individuals from states with fewer than 2,500 observations. Additional estimations were conducted in which we also dropped all individuals with household incomes below $10,000, in an attempt to exclude those with potentially subsidized electricity prices (e.g., in subsidized housing) or nondeclared income sources. The results of this estimation, by GMM, are presented in Table 8. The price elasticity estimates are nearly identical to those in Table 6, where there was no censoring based on income. The changes in income elasticities are more noticeable. For example, it increases from 0.071 to 0.102 for the Northeast region. This suggests that households with incomes below $10,000 have smaller income elasticities.

The purpose of dropping observations in the top and bottom 2.5 percent of electricity expenditure is to remove outliers and to obtain a better approximation of the average-price schedule using a linear function. The next specification, in which we drop observations in the top and bottom 1 percent of electricity expenditure, examines the sensitivity of the results with respect to this censoring. The results, presented in Table 9, are close to the results from the baseline model in Table 6. The biggest change in price elasticity estimates is for the West region, where it changes from 0.878 to 0.915.

All previous specifications use 10 cost shifters as instruments for electricity price to form moment conditions. The last alternative specification uses 5 of the 10 lagged cost shifters employed in the baseline model: the average share of electricity generated by coal during the past 12 months, that by natural gas, that by nuclear and hydropower, the interaction between the average coal price during the past 12 months and the coal share of generation, and the interaction between natural gas price and the natural gas share of generation. The other five variables not used in this specification are those measured based on quarterly averages. Table 10 shows the parameter estimates for the demand equations for the four regions. Most of the estimates are very similar to those from the baseline model in Table 6. The noticeable differences are in price elasticity estimates for the Northeast and Midwest regions: they are 0.74 and 1.02 in this specification compared to 0.82 and 0.96 in the baseline model. Nevertheless, demand is still more price elastic in the South and Midwest regions than in the other two regions.

VI. Policy Analysis Simulations

As discussed above, our price elasticity estimates are considerably larger than those based on the assumption of marginal-price responsiveness. The question, however, remains as to how these different estimates will alter analyses of federal policies that affect electricity prices. To examine this issue, we use simulations to study a federal carbon dioxide (CO_2) emissions regulation similar to that proposed in H.R. 2454 (U.S. House of Representatives 2009), the Waxman–Markey climate bill.

The simulations are conducted using Resource for the Future's Haiku electricity market model,[12] a deterministic and highly parameterized simulation model of the electricity sector in the 48 contiguous U.S. states. It calculates information similar to that of the Electricity Market Module of the National Energy Modeling System that is maintained and used by EIA. This analysis hinges on the demand side of the Haiku model, which employs a partial adjustment specification of electricity demand.

We conduct the simulations under three different residential price elasticity of demand parameterizations. In the first parameterization, we use the rather low short-run price elasticity estimates generated by Paul et al. (2009b) that vary by region and season. We denote this the ε_L case to signify the low elasticity estimates.[13] The Paul et al. (2009b) model was based on state-aggregated data and includes both short-run and long-run elasticity estimates. In the second parameterization, we replace the short-run price elasticities of Paul et al. (2009b) with a more moderate estimate of –0.4, the ε_M case. This value is in line with the price elasticity estimated in Reiss and White (2005) which, as stated above, is based on marginal-price responsiveness from household-level data in California.[14] This elasticity is applied to all regions covered under the simulation. In our final parameterization, we use the region-specific price elasticities estimated above as the short-run elasticity in the policy simulation. We denote this the ε_H case to signify our higher elasticity estimates. All other features of the model, such as long-run price elasticities, other residential demand covariates, and all of the coefficients for the industrial and commercial sector demand functions, are those estimated in Paul et al. (2009b).

[12] Complete model documentation is available in Paul et al. (2009a).

[13] The regionally specific residential short-run elasticity estimates in Paul et al. (2009b) range from –0.01 to –0.32, with a national average of –0.13.

[14] Note that Reiss and White (2005) estimate end use-specific elasticities. The value –0.4 is in line with their average elasticity estimate across these end uses and across households in their sample.

The simulation outputs give us, among many other variables, average residential electricity prices and total consumption at the region level and national CO_2 emissions allowance prices. The model is run over the 2010 to 2035 horizon, with the CO_2 emissions control policy beginning in 2012 and holding cumulative economywide CO_2 emissions constant across scenarios.[15] We show the policy simulation results for four years (2012, 2016, 2025, and 2035) for each of the parameterization cases. We also show percentage changes relative to the *Annual Energy Outlook 2010* reference case (U.S. EIA 2010). National results are given in Table 11, and regional results are in Table 12.

The national-level results show that the policy tends to increase electricity prices relative to the reference case and that the price impact tends to grow over time. The details of why this pattern emerges are not important for this analysis, but it hinges on a leftward shift of the electricity supply curves, and we are interested in how the assumption about short-run price elasticities impacts consumption, electricity prices, and allowance prices under this supply-side shift. The simulations show that, especially in the long run, federal climate policy will engender a significantly greater reduction in electricity consumption if consumers are more price elastic. This may have important negative welfare consequences for households, though it will be partly offset by a corresponding reduction in allowance prices. By 2035, the allowance price under the ε_H scenario is 4 percent lower than under the ε_L scenario. This would have a positive welfare impact on households because, under an economywide emissions cap, all goods and services that have any carbon intensity of production will become more expansive as allowance prices rise.

Another factor that mitigates the household welfare impacts of consumption reductions is the electricity price. Table 11 shows an approximate \$3/MWh difference in electricity prices from the ε_L case to the ε_H that holds fairly constant throughout the time span examined. The price difference may seem surprisingly low given the rather large differences in electricity consumption from ε_L to ε_H, however the demand parameters of the other customer classes (commercial and industrial) are held constant across these scenarios, and these residential consumption reductions represent only a part of total electricity demand. Furthermore, the electricity price reductions that emerge under the higher elasticity scenarios result in an increase in consumption by the other customer classes. These factors, along with the observation that the

[15] Haiku includes a marginal abatement cost curve that allows for allowance price-responsive rest-of-economy emissions. It also includes supply curves for domestic and international carbon offsets that are constrained according to the offsets specification of H.R. 2454.

long-run supply curves for electricity production in Haiku are relatively elastic, yield relatively small changes in electricity price.

The region-specific price and consumption patterns largely follow the national patterns, but there are some differences. For instance, in the West region, we find very little difference in electricity prices across elasticity parameterizations, whereas in the Midwest, the price differences from ε_L to ε_H are much more pronounced. This is largely due to the differences between these regions in production technologies. The West region has significant hydroelectric generation and resources for nonemitting renewable electricity production. Thus, the region will incur a relatively small shift in electricity production costs as a result of this cap-and-trade system, and therefore small price increases. Conversely, electricity generation in the Midwest region is predominantly from coal, which will incur the largest shift in production costs with the introduction of an emissions price. The larger shift in the supply curve will, of course, lead to larger price differentials across the elasticity parameterizations. We also find that, unlike the price pattern observed at the national level, electricity prices in the Northeast and Midwest regions are not strictly increasing over time. This is due to the timing of investment in nuclear capacity and the retirement of existing capacity in these regions.

We generally find decreasing regional consumption as we go from the ε_L to ε_H parameterizations, as in the national results. An exception to this is the consumption pattern in the South region in 2012. For that year, we see that consumption under the ε_H setting is actually greater than that under the ε_L parameterization. How can this be? The answer is, in part, due to the complex dynamic investment decisions faced by generation capacity owners. In this particular case, the inclusion of an allowance price leads to greater generation revenues for marginal natural gas electricity generators, particularly in later years of the policy as allowance and electricity prices increase. Electricity prices also include the cost generators incur to have excess reserve capacity that is needed only in the highest demand periods, which we call the reserve cost. Because generators earn larger generation revenues in later periods under a cap-and-trade policy, the equilibrium reserve costs are lower in the near term compared to a case with no emissions control policy. Depending on the price elasticity assumptions, which affect both the emissions allowance price in general and the electricity price, the long-run investment choices may be such that increasing allowance prices lead to a decrease in reserve costs that more than offset the increase in generation costs due to an emissions price. The elasticities under the ε_H setting, combined with the generation technologies of the South region, lead to just such an outcome.

In general, this simulation example yields mostly predictable results, particularly when viewed in aggregate at the national level. However, the results do show some regional differences that highlight how changes in the elasticity assumptions can lead to some particularly interesting and nonintuitive regional pricing and consumption patterns under an electricity price-raising cap-and-trade policy.

VII. Conclusion

Given the recent push to craft a federal energy policy in the U.S., —in which alterations to the portfolio of electricity generators, and therefore to electricity prices and consumption, are likely to be central components—there is a pressing need to obtain accurate electricity demand estimates for all parts of the country. Undertaking such a task poses several challenges, most notably that electricity rate structure data for all parts of the U.S. are not easily obtainable. Hence, most electricity demand models that use household-level data are conducted for very specific regions for which the researchers were able to obtain specific rate structure data.

To avoid the need for specific rate structure data, we develop a novel GMM approach that allows us to recover residential electricity demand parameters and average-price schedule parameters based on electricity expenditure data (along with demand covariates and some other easily obtainable aggregate price and quantity information). We then apply this technique to detailed household-level data in the CEX, which includes monthly household electricity expenditures, but not electricity prices or quantities, over the period 2004–2006. We estimate demand and average-price schedule equations for four census regions separately.

We find that price elasticities vary across the four census regions, with the South region having the most price-elastic demand with an elasticity of –1.02 and the Northeast region having the least price-elastic demand at –0.82. In general, these price elasticity estimates are considerably larger in magnitude than those of other studies of residential electricity demand using household-level data. As we show through a simple example, it is not unreasonable for our estimates to be larger than those derived in studies that assume that households respond to marginal electricity prices because we explicitly assume that households respond to average electricity prices. As noted above, several studies present some empirical evidence, albeit confined to specific geographic regions, to support the notion that average-price responsiveness is a more appropriate assumption than marginal-price responsiveness.

To put these elasticity estimates into a policy-relevant perspective, we conducted a policy study, using a model parameterization based on the estimates derived here, to simulate the recently proposed U.S. climate policy legislation, H.R. 2454 (Waxman–Markey). The outcomes from this policy study, in terms of regional and national electricity prices, consumption, and emissions allowance prices, were then compared to outcomes using more conservative price elasticity parameterizations, typical of marginal price-responsive demand estimation studies. Not surprisingly, we find that, on a national level, simulations using the elasticity estimates derived here compared to more conservative elasticity estimates leads to a greater reduction in electricity consumption as a result of the implementation of the policy and lower emissions allowance prices. From a regional perspective, we find that the decreases in consumption brought about by the policy are not uniform and have considerable heterogeneity depending on the elasticity used. In fact, we find that in the South region, using our larger price elasticities leads to a near-term increase in electricity consumption under the policy relative to the no-policy baseline and relative to the more conservative elasticity parameterizations. This result is due to the complex interaction of dynamic capital investment decisions and price elasticities embedded in our analysis framework. Furthermore, this regional result highlights the important role elasticity assumptions can play in expected policy outcomes.

Though we believe this study provides a novel approach to estimating electricity demand without specific rate structure data and provides valuable regional elasticity estimates, it leaves several issues unexplored. First, because we do not have specific bill information, we cannot validate our average price-responsiveness assumption. This is clearly an important consideration that goes far beyond the current study. In addition, because of the short time frame examined, we do not account for capital adjustment by households. Estimating capital adjustment price responses, and how these responses vary across income groups, would be very valuable in determining the expected outcomes of national energy policies aimed at improving energy efficiency. However, such estimates would require more detailed data than what is available in the CEX.

A B S T R A C T

Recent empirical research for different regions of the United States indicates that residential electricity may be an "inferior" good whose consumption is negatively correlated with income. That is a provocative result that runs counter to what many earlier econometric studies indicate. Given that, it makes sense to examine how electricity consumption behaves in different regional service areas. Even if residential electricity is an inferior good whose usage declines as income rises, there is no guarantee that this will be the case across all service areas. This study examines residential electricity consumption for Seattle, Washington, the largest metropolitan economy in the northwestern region of the United States. Results from a dynamic error correction modeling approach indicate that residential electricity consumption reacts in statistically significant manners to changes in real price, real income, and cold weather. In the short-run, residential electricity is a normal good in this metropolitan economy. In the long-run, residential electricity appears to be an inferior good in Seattle. All else equal, whenever real per capita income growth exceeds 1.2%, per capita residential electricity usage declines in Seattle.

1. Introduction

Recent empirical evidence indicates that residential electricity is an inferior good at the state level across the United States (Contreras et al., 2009). This is an interesting possibility that is at odds with a number of prior studies but it overlooks the fact that electricity in the United States tends to be generated, transmitted, distributed, and sold within sub-state regional and municipal service areas. Given the latter, there is no guarantee that econometric results obtained from national data samples of state level electricity usage will also be observed within individual electric utility service areas. Material in this study examines residential electricity consumption for Seattle, Washington, the largest metropolitan economy in the northwestern region of the United States.

Seattle is the economic fulcrum of King County, and is the center of entertainment and employment for citizens located in parts of Snohomish, Pierce and Kitsap Counties. Lying on an isthmus between Puget Sound and Lake Washington, Seattle is an economic hub for trade, tourism and technology. Seattle City Light (SCL) is the public electric utility that provides service to number of sub-regions within the Seattle MSA: Burien, Lake Forest Park, Normandy Park, Renton, SeaTac, Seattle, Shoreline, Tukwila, First Hill and University District. A public monopoly, SCL is the sole provider of electricity in this market and is a department within the Seattle city government.

The King County population estimate for 2007 is 1,861,300 residents. King County nominal per capita personal income in 2007 is $57,710 and has grown at a compound annual growth rate of roughly 5.4% from 1969 forward. The 2007 unemployment rate for King County was 3.8%. The median price for existing houses was $284,996. The number of SCL customers in 2007 was 343,542, an increase of 39% from 1960. This market growth has occasionally resulted in significant off-system power purchases. Total electricity consumption in 2007 reached 3,103,550,000 kilowatt hours (KWH). From 1960 through 2007, the SCL nominal average price per KWH increased from $0.00965 to $0.0632.

Seattle is one of the more unique electricity markets in the United States. SCL distributes electricity generated by hydroelectric plants. Its primary off-system purchases are from electricity generated by dams located on the Columbia River. Federal laws favor the supply of electricity from these generators to public utilities and results in relatively low residential rates for SCL consumers. To date, few empirical analyses of SCL residential electricity consumption have been completed and the manner in which residential usage reacts to income gains has not been documented. Accordingly, one possibility investigated in this effort is whether electricity is an inferior good in the SCL market (Contreras et al., 2009; Roth, 1981).

2. Literature review

Earlier empirical work in residential electricity consumption examined whether the inclusion, or exclusion, of either marginal price or average price in demand equations will generate biased parameter estimates and hamper model simulation capabilities. Marginal rates are determined by negotiations between utility suppliers and regulatory oversight bodies regarding specific quantities of purchased electricity. Taylor (1975) argues that both average price and marginal price

doi:10.1016/j.eneco.2012.02.004

should be included in econometric electricity demand studies to capture income and substitution effects, respectively. It has also been argued that, because of the differing marginal rates among various electricity suppliers, employment of either price metric may be acceptable (Fisher and Kaysen, 1962). Cicchetti and Smith (1975) note that average price measures are often employed as a consequence of data constraints. Empirical results reported in that study indicate that approach may be superior to attempting to create marginal rates from representative customer bills. Fisher and Kaysen (1962) utilize average price for a pooled cross sectional time series study of residential electricity consumption in the 48 contiguous states. Anderson (1973) also models residential usage for California with an average price variable. Both studies indicate that decreases in electricity consumption as a response to increases in average price are less than proportional. Price inelastic residential electricity demand has been confirmed in a very large percentage of subsequent empirical studies (Dergiades and Tsoulfidis, 2008).

Among residential electricity studies employing both price metrics is Roth (1981). Equation estimates in that effort rely on data from an individual southwestern region utility in the United States. Results obtained indicate that electricity is an inferior good for the market in question. This is an intriguing result because it implies that higher income levels will not lead to greater electricity consumption by residential customers. Contreras et al. (2009) report a similar result using national residential electricity consumption data and note that the increased energy efficiencies of higher quality, and higher priced, home appliances may contribute to this finding.

Maddigan et al. (1983) estimate rural residential electricity consumption. That study takes into account one important problem with the employment of an average price variable, endogeneity. A price equation is estimated in an attempt to maintain consistency between total revenue and average price. Empirical results obtained are consistent with prior findings documented in other studies (Anderson, 1973; Fisher and Kaysen, 1962; Wilson, 1971). Out-of-sample forecasting results are also found to compare favorably to than those for a benchmark alternative.

Recent research has pointed to several potential shortcomings associated with marginal price approaches. Among them, a problem arises with the assumption that consumers perfectly optimize utility, or more explicitly stated, respond instantaneously to changes in marginal price. Such a perfectly informed customer is rare and unrealistic. Consumers do not respond directly to a change in marginal price, but rather to the price received at the end of a billing period. Such an assumption does not properly reflect consumer response to a block-rate pricing structure (Borenstein, 2009).

Shin (1985) reports evidence that indicates that average electric rate estimates provide accurate information for the analysis of residential electricity consumption. That study emphasizes that consumers may refer only to average rates when pricing structures make accurate marginal rates costly to obtain or understand. Similar approaches have been utilized in the analysis of municipal water utility consumption trends (Fullerton and Molina, 2010). As with electric utilities, the latter approach is frequently employed when block rate schedule and consumption data are incomplete.

A variety of time series approaches, including error correction models (ECMs), have also been employed in several recent efforts (Dergiades and Tsoulfidis, 2008; Hacioglu, 2007; Zachariadis and Pashourtidou, 2007). ECMs examine long-run equilibrium relationships and also introduce past short-run disequilibria as an explanatory variable of the dynamic behavior of current period variables (Maddala and Kim, 1998). Given the comprehensive allowance for both long-run and short-run behavior, ECMs offer some obviously attractive features for the analysis of electricity consumption patterns.

Among the explanatory variables commonly found to assist in the empirical analysis of residential electricity usage are price, income, and climatic measures. Negative income elasticities reported in Narayan et al. (2007) indicate that residential electricity is an inferior good in those economies. Whether those results are universal among all regions in those countries is not known at this juncture. Own-price elasticities tend to be negative and inelastic in a very high percentage of these efforts (Espey and Espey, 2004). The exact nature of climate impacts on electricity consumption varies substantially.

Similar to many northern hemisphere electric utilities, SCL residential peak usage occurs during the winter months. Commonly employed weather variables for demand equations include heating degree days, cooling degree days, and ambient mean temperature (Lam et al., 2008; Narayan et al., 2007; Wangpattarapong et al., 2008; Zachariadis and Pashourtidou, 2007). Residential consumption equations for utilities located in cooler climates frequently use heating degree days (HDD) as regressors and omit cooling degree days from the specifications (Filippini, 1995). Using a base temperature of 65 °F, HDD is calculated as 65 – DAT, where DAT stands for daily average temperature. For days in which the average temperature exceeds 65 °F, HDD is assigned a value of zero.

3. Data and theoretical model

Annual data for the analysis come from SCL annual reports (SCL, 2010). The data are from 1960 to 2007. Consumption data include total residential consumption in megawatt hours (MWH) and the number of customers. Revenue statistics include total revenue, average revenue per customer, and average revenue per kilowatt hour (KWH). As in a number of other studies, average revenue per KWH is used in this effort as the price variable (Espey and Espey, 2004; Shin, 1985).

Under the SCL current pricing structure, the block rates for residential customers are increasing. The rate schedule varies among different cities within the service area because the cost to provide electricity is not uniform across the service area. Because SCL is a public utility, rates are attempted to be set so that no one area subsidizes another. Beyond that, rates are set to solely cover the cost of producing, transmitting, and distributing electricity. This approach to rate setting differs from that of a private utility service provider where profit maximization within a regulated rate environment applies. Data constraints regarding historical and cross-jurisdictional rate schedules prevent calculating marginal price tariffs (Williams and Suh, 1986). In addition to the lack of detailed rates information, historical records for cross-jurisdictional consumption patterns are also incomplete.

Per capita income is used to account for cyclical economic influences on electricity consumption. Per capita income data for Seattle are reported by SCL using information from the United States Bureau of Economic Analysis and the Washington State Employment Security Department. The Seattle consumer price index from the U.S. Bureau of Labor Statistics (BLS) is used to deflate the price and income data (BLS, 2010).

Residential electricity is consumed through surrogates such as televisions, washers, dryers, stoves, personal computers, and other electricity using durable appliances. Space heaters and air conditioners are used to relieve seasonal weather conditions and can increase the amount of electricity consumption for a given household. Historical stock data for these household appliances are lacking. As a result, proxies must be used to account for stock durables and seasonal fluctuations.

The number of customers will be used to account for the stock of consumer durables. As the number of customer households increases, the need to obtain electrical, and other, appliances for everyday living will rise (Dergiades and Tsoulfidis, 2008). Customers are measured as the average numbers of active meters annually billed by the utility (SCL, 2010).

A northern hemisphere city located near the Pacific Ocean, Seattle observes relatively moderate summer temperatures. Dating back to 1960, the average temperatures during the summer months of June, July and August have consistently remained below 70 °F (WRCC, various issues). Given that, cooling degree days is not included in the model specification below. Heating degree days (HDD) data are reported for Seattle (WRCC, various issues) and are used as a surrogate for climatic conditions influencing heating systems use (Dergiades and Tsoulfidis, 2008; Filippini, 1995).

Aggregate residential electricity demand is assumed to be functionally dependent on price, personal income, the number of customers, and climatic factors during cold weather months. Long-run consumption per customer is specified in Eq. (1). In Eq. (1), KWHC is kilowatt hours per customer and YCAP is real per capita income calculated as nominal per capita income divided by the by the Seattle consumer price index reported by the U.S. Bureau of Labor Statistics. PCPI is the SCL average price per kilowatt hour, also deflated by the Seattle consumer price index, HDD is heating degree days, u is a random disturbance term, and t is an annual time period index. Because natural logarithmic transformations are utilized, the parameters represent elasticities of demand.

$$\mathrm{Ln(KWHCt)} = \alpha 0 + \alpha 1\mathrm{Ln}\underset{(+)}{(\mathrm{YCAPt})} + \alpha 2\mathrm{Ln}\underset{(-)}{(\mathrm{PCPIt})} + \alpha 3\mathrm{Ln}\underset{(+)}{(\mathrm{HDDt})} + \mathrm{ut} \tag{1}$$

Numbers in parentheses under Eq. (1) represent the expected signs of the slope coefficients. Growth in real per capita income will increase consumption per customer if residential electricity is a normal good. The latter occurs if increases in real income lead to greater purchases of and more usage of electricity using household devices (Silk and Joutz, 1997). However, as results in other studies indicate (Contreras et al., 2009; Roth, 1981), residential electricity, in some markets, may be an inferior good.

The price coefficient is expected to be negative as increases in price will typically lead to a reduction in the consumption of a good or service. The latter implicitly assumes that electricity consumption will not be conspicuous in nature (Grinblatt et al., 2008). The parameter sign for HDD is hypothesized as positive sign because ambient temperatures below the baseline mark (65 °F) will increase the need for heating (Dergiades and Tsoulfidis, 2008).

The long-run relationship shown above is known as the cointegrating equation. It represents how equilibrium per customer electricity consumption evolves over time. Deviations away from long-run consumption equilibrium can occur due to a variety of circumstances such as aging household appliance stocks, income shocks, and other factors (Greening and Sanstad, 1996). Those deviations will generally begin to dissipate in the quarter after when they occur, but may not completely be offset for several periods. Any deviation from the long-run equilibrium will, therefore, affect subsequent short-run consumption patterns.

Eq. (2) permits examining short-run characteristics of residential electricity consumption that take into account the potential impact of consumption deviations relative to the long-run. In Eq. (2), d is a difference operator and v_t is a random disturbance term. The error correction term is u_{t-1}, the prior period disturbance from the cointegrating equation. Numbers in parentheses below Eq. (2) indicate the hypothesized for the respective parameters. The coefficient for the error correction term is expected to be less than zero since deviations from equilibrium consumption levels will precipitate offsetting adjustments in the subsequent period. The speed of adjustment to any prior quarter shocks will depend upon the magnitude of b4. Because many electrical appliances are highly durable and expensive, one potential source of residential consumption disequilibria is a relatively slow appliance stock replacement rate.

$$\mathrm{dLn(KWHC_t)} = b_0 + b_1\mathrm{dLn}\underset{(+)}{(\mathrm{YCAP_t})} + b_2\mathrm{dLn}\underset{(-)}{(\mathrm{PCPI_t})} + b_3\mathrm{dLn}\underset{(+)}{(\mathrm{HDD_t})} + \underset{(-)}{b_4 u_{t-1}} + v_t \tag{2}$$

For nearly all public utilities, understanding changes in the numbers of customers from period to period is fairly important. Growth in the number of accounts requires planning for the service expansion as new meters, sub-stations, and distribution lines must be installed for new neighborhoods and residences. Accordingly, an equation is also specified for the number of customers. In many cases, utility customer base increases will be affected by both demographic and economic trends and developments (Fullerton et al., 2007). Such an approach is utilized in the error correction framework shown below for SCL residential accounts. In Eq. (3), POP is defined as the population of the SCL service area and EMP stands for non-agricultural wage and salary employment, also in the SCL service area. Both explanatory variables are expected to be positively correlated with the number of SCL residential customers.

$$\mathrm{LnCSTM_t} = c_0 + c_1\mathrm{Ln}\underset{(+)}{(\mathrm{POP_t})} + c_2\mathrm{Ln}\underset{(+)}{(\mathrm{EMP_{t-1}})} + g_t \tag{3}$$

The short-run error correction specification is shown in Eq. (4). Numbers in parentheses indicate the hypothesized signs for each of the parameters in the equation. Disequilibria in the customer base may result from delays in housing construction and/or problems faced by new migrant in acquiring new residences within the SCL service area. Any prior-period deviation away from the equilibrium number of customers is expected to be partially offset in the subsequent year. The time required to total dissipation will depend upon the magnitude of f_3 in Eq. (4).

$$\mathrm{dLnCSTM_t} = f_0 + f_1\mathrm{dLn}\underset{(+)}{(\mathrm{POP_t})} + f_2\mathrm{dLn}\underset{(+)}{(\mathrm{EMP_{t-1}})} + \underset{(-)}{f_3 g_{t-1}} + h_t \tag{4}$$

4. Estimation results and empirical analysis

Because KWH consumed appears on both sides of Eq. (1), the manner in which the average price variable is calculated raises the specter of potential simultaneity. An artificial regression procedure is used to test this possibility (Davidson and MacKinnon, 1989). The null hypothesis tested is that the average price variable (PCPI) does not have an endogenous relationship with the kilowatt-hour per customer dependent variable (KWHC). If that hypothesis is rejected, it implies that ordinary least squares estimates of Eq. (1) will be inconsistent. This bi-directional relationship could generate a contemporaneous correlation between the endogenous independent price variable and the error-term (Pindyck and Rubinfeld, 1998).

To carry out the endogeneity test, two instrumental variables are utilized. The first is the national fixed asset price deflator for electric power structures (STRUC). That variable is selected because SCL's rates and revenues are based upon operating and capital costs of the federal electric power system. The latter is principally comprised by dams and transmission facilities (Lee et al., 1980). The second instrument is the national electricity price index (ELECP). National electricity prices affect the rate SCL is charged for off-system power purchases, and the rate SCL charges other electricity utility companies. Both of the instrumental variables are obtained from the Bureau of Economic Analysis national income and product account tables (BEA, 2010).

The null hypothesis, H0, that PCPI is not correlated with the error-term in Eq. (1) is rejected at the 1-percent level. That is similar to what has been documented in earlier electricity studies (Henson, 1984; Wilder and Willenborg, 1975). Given the simultaneity outcome, a price equation is estimated to provide fitted price values (PCPIHAT). The specification for the latter is shown in Eq. (5). It utilizes two of the exogenous variables from Eq. (1) plus both of the instrumental variables employed in the artificial regression test. Although SCL is one of the larger public utilities in the United States, it not so large that its rates would influence either of the instruments. Fitted values, PCPIHAT, from the estimated version of Eq. (5) provide

Table 1
Residential electricity consumption in Seattle.

Variable name	Definition
KWHC	Kilowatt hours per customer
YCAPC	Real per capita personal income
PCPIHAT	Fitted values for average electricity price
HDD	Heating degree days
RESIDLR	Residual error term from long-run kilowatt hours per customer equation
POP	Population
EMP	Employment

the average price measure used in the empirical results shown below (estimation results for Eq. (5) are available from the authors).

$$\mathrm{LnPCPIt} = \mathrm{C0} + \mathrm{C1LnYCAPCt} + \mathrm{C2LnHDDt} + \mathrm{C3LnSTRUCt} + \mathrm{C4LnELECPt} + \mathrm{mt} \tag{5}$$

Table 1 lists all of the variable names assigned to the data used for the empirical analysis. Table 2 reports the estimation results for cointegrating demand function in Eq. (1) with the fitted values for the average price variable, PCPIHAT. The modified long-run demand specification is shown in Eq. (6). Each of the coefficient estimates satisfies the 5-percent significance criterion. Overall diagnostics shown in Table 2 are favorable. Although the Durbin–Watson statistic indicates that the residuals are positively correlated, experimentation with a variety of alternative specifications including both autoregressive and moving average coefficients did not yield superior results (Pagan, 1974). A unit root test confirms that a cointegrating relationship exists (Kennedy, 2003).

$$\mathrm{Ln}(\mathrm{KWHC_t}) = \alpha_0 + \alpha_1\mathrm{Ln}(\mathrm{YCAPC_t}) + \alpha_2\mathrm{Ln}(\mathrm{PCPIHAT_t}) + \alpha_3\mathrm{Ln}(\mathrm{HDD_t}) + \mathrm{u_t} \tag{6}$$

Real average price (PCPIHAT) and annual heating degree days (HDD) exhibit the hypothesized signs. An increase in the real price leads to reduced residential electricity use. The magnitude of the price elasticity is somewhat lower, in absolute terms, than some of those reported other in other recent studies (Hacioglu, 2007; Narayan et al., 2007; Zachariadis and Pashourtidou, 2007). It is, however, well within the range of price elasticities that have been historically estimated for residential electricity usage (Espey and Espey, 2004).

Results for the cointegrating equation in Table 2 indicate that cold weather leads Seattle residents to increase electricity consumption. A 1-percent increase in annual heating degree days (HDD) increases residential usage by approximately 0.3%. This elasticity estimate is in line with those reported in similar analyses (Dergiades and Tsoulfidis, 2008). Interestingly, Maddigan et al. (1983) find that rural customers in the northwest region respond more to fluctuations in temperature than to changes in price. To the extent that climate change may lead to more extreme low temperatures during the winter months, the HDD coefficient indicates that SCL residential demand may grow substantially in future years (Zachariadis, 2010).

In Table 2, the negative sign for the real per capita income (YCAPC) parameter indicates that, over the long-run, residential electricity is an inferior good within the SCL service area. That result differs from many studies, but has been documented for other regional electricity markets in the United States (Contreras et al., 2009; Roth, 1981). Over the long-run, a 1% increase in real per capita income is associated with a 0.29% reduction in SCL household electricity consumption. If Seattle metropolitan economy per capita incomes improve in real terms, as they have over the course of four plus decades, SCL residential sales will place less of a burden on the overall system load than otherwise would generally be anticipated.

Results for the short-run parameter estimates are shown in Table 3. All of the computed *t*-statistics for the regressor coefficients satisfy the 5-percent criterion. The statistically significant and negative constant term implies that SCL residential electricity usage has become steadily more efficient over the course of the sample period. The real per capita income (YCAPC) coefficient is positive, indicating that SCL household customers treat electricity as a normal good in the short-run. Because appliance stocks are largely fixed in the short-run, that is a reasonable outcome. The price (PCPIHAT) elasticity in Table 3 is negative and smaller, in absolute magnitude, than its long-run counterpart above (Dergiades and Tsoulfidis, 2008). The climate (HDD) coefficient indicates that SCL residential electricity consumption is fairly sensitive to ambient temperature declines. The latter result potentially reflects the high number of electric heating systems found in the Seattle metropolitan economy.

The residual series from the long-run estimation is used as a proxy for deviations from the long-run consumption equilibrium. As hypothesized, the sign of the error-correction parameter is less than zero. The magnitude of that coefficient indicates that approximately 19.2% of any adjustment toward consumption equilibrium occurs during the first year following a deviation from it. A total of approximately 5.2 years are required for any prior-period consumption deviations away from the equilibrium level to fully dissipate.

To test the stability of the long-run coefficients, cumulative sum (CUSUM) and cumulative sum of squares tests (CUSUMQ) are carried out on the residuals of the error-correction model specified in Eq. (6). A CUSUM stability test measures the systematic movements of the coefficients. The null hypothesis tested is that of coefficient stability. H0 is rejected if the cumulative sum exceeds the specified critical boundaries, demonstrating instability among the coefficients (Maddala and Kim, 1998). A CUSUMQ test measures variance stability. Both tests reveal coefficient and variance stability as the residuals and squared residuals move within their respective 5-percent critical boundaries, failing to reject the respective null hypotheses.

A natural question arises with respect to the seemingly contradictory short-run and long-run income elasticities reported in Tables 2 and 3. At least part of the explanation probably relates to technological advances in energy efficiency (Borg and Kelly, 2011). Income growth is strongly influenced by technological progress (see, for example, Venturini, 2009). Changes in technology and energy efficiency would not, however, be correlated with short-run transitory fluctuations in personal income. Consequently, long-run income gains are likely to be inversely related to household electricity usage, but short-run income variations will be positively correlated with electricity consumption. Based on the estimation results reported in Tables 2 and 3, whenever real per capita income grows by approximately 1.2% or more, residential electricity usage per capita should, all else equal, decline.

The investment requirements associated with capacity development make it important for public utilities to anticipate service growth. To do so requires understanding how the customer base is likely to expand. Population and employment are used as the explanatory variables to account for both economic and demographic factors affecting SCL residential customer growth. The basic specification shown above in Eq. (3) has also been applied to water utility accounts models (Fullerton et al., 2007). Estimation results for Eq. (3) appear in Table 4 and exhibit fairly good statistical traits.

The coefficient of determination, adjusted for degrees of freedom, indicates that approximately 97 percent of the variation in the dependent variable is explained by the equation. The computed *t*-statistics for the regression parameters all satisfy the 5-percent criterion. The slope coefficient magnitudes indicate that 1-percent increases in SCL service area population and/or employment increase the customer base by approximately 0.46%, each. The Durbin–Watson statistic suggests the presence of positive serial correlation. Estimation of an autocorrelation function (ACF) also indicates the presence of serial correlation. In spite of the latter, a variety of autoregressive, moving average, and mixed nonlinear specifications yield coefficients that fail to satisfy the 5-percent criterion (Pagan, 1974). A unit root test conducted with the residuals confirms that a cointegrating relationship exists (Kennedy, 2003). To test for consistency of the long-run multipliers, CUSUM and CSUMSQ tests are run (Maddala and Kim, 1998). Both of those tests indicate coefficient stability for the outcomes reported in Table 4.

A short-run error correction equation is also estimated for SCL residential customers using the specification shown above in Eq. (4). Estimation results are reported for it in Table 5. The statistically significant constant term reflects steady annual increases in the number of SCL residential customers. The parameter estimate for population is not significantly different from zero. The latter is not surprising since many population changes such as births, deaths, household departures, or new arrivals do not necessarily result in either more or fewer SCL residential accounts.

Table 5
Short-run equation for SCL residential customer base.

The coefficient estimated for lagged employment does satisfy the 5-percent significance criterion. That result also makes practical sense. New employment is more likely to lead to new customer accounts than is population gain. The converse also holds, an important point for a fairly cyclical economy such as Seattle's. The error correction parameter in Table 5 is not significantly different from zero. The overall results for Table 5 indicate that short-run variations in the SCL residential customer base are not easily modeled, but grow steadily and are affected by prior period employment changes.

As an additional step toward examining empirical reliability of the estimation results, a 3-period out-of-sample forecast is simulated for KWHC and CSTM. The forecast period employs the compound annual growth rates (CAGR) from 2004 to 2007 for each of the respective explanatory variables. This follows the Lakhani and Bumb (1978) approach for basic electricity forecasting assessment. HDD is the only variable for which no growth is assumed and the historical mean of 4837 is used (Fullerton and Molina, 2010). It should be noted that the CAGR historical sample occurred before the financial market collapse of 2008 and the simulation is not intended to examine the cyclical extrapolation properties of the residential equations for the SCL service area.

Table 6 reports the estimated CAGRs for each of the explanatory variables. Real per capita income has a CAGR of 1.375%. The CAGR for the fitted price variable, PCPIHAT is −2.339%. The SCL nominal price per KWH decreased by 0.842% from 2004 to 2007. That, in combination with the increases in the Seattle CPI, results in a real price per KWH CAGR decline of 2.339%. Population in the SCL service area increased at a CAGR of 0.413%. Employment rose 1.7854% exceeding the population growth experienced over that same 3-year period.

Table 7 reports the forecasts for the dependent variables and their respective percentage changes between the forecast periods. Because the effects of the real price decline outweigh the impacts of the real income growth, kilowatt-hours per customer are forecast grow from

Table 6
Explanatory variable growth.

	YCAPC	PCPIHAT	HDD	POP	EMP
CAGR (%)	*1.375*	*−2.339*	*0.000*	*0.413*	*1.785*
Year 1	24,942	2.9503	4,837	749.282	592.798
Year 2	25,286	2.8813	4,837	752.376	603.382
Year 3	25,633	2.8139	4,837	755.482	614.154

Notes:
Percentage compound annual growth rates, CAGR%, for 2004 to 2007 for each explanatory variable are italicized.
Per capita income, YCAPC, is shown in real dollars, 1982–84 = 100.
Price per kilowatt hour, PCPIHAT, is shown in real cents per KWH.
HDD stands for annual heating degree days.
Population, POP, and employment, EMP, are measured in thousands for the SCL service area.
Data may not match due to rounding.

Table 7
SCL residential consumption and customer forecasts.

YR	KWHC	%Δ	MWH	%Δ	CSTM	%Δ
1	9579	–	3,227,634	–	336,949	–
2	9623	0.46	3,275,332	1.48	340,365	1.01
3	9668	0.47	3,324,013	1.49	343,816	1.01

Notes:
KWHC is kilowatt-hours per customer.
MWH is megawatt-hours.
CSTM is the number of residential customers.

9,579 in Year 1 to 9,668 in Year 3. SCL residential customers grow by approximately 1.0% per year, reaching 343.8 thousand by the third year of the simulation. Together, the per capita consumption and customer base growth patterns imply that SCL residential MWH usage would expand by approximately 1.5% per year. Those forecasts fall within observable historical norms for the residential rate class of this electric utility, indicating that model simulation performance is at least plausible for recently observed conditions in the Seattle metropolitan economy.

5. Conclusion

To analyze residential electricity demand in the Seattle City Light service area, error-correction models are estimated for per customer consumption and the number of residential customer accounts. Price is approximated using a cent per kilowatt hour average revenue measure. Not surprisingly, artificial regression test outcomes indicate simultaneity exists between the consumption and price variables. Consequently, fitted price values from an instrumental variables equation are utilized for the long-run and short-run per customer consumption equations.

Similar to what has been documented for other regions, SCL residential consumption responds in an inelastic manner to price changes, especially so in the short-run. The cointegrating equation income elasticity is negative and statistically significant, indicating that electricity is an inferior good in Seattle over the long-run. That outcome has also been reported for other residential electricity markets and for the United States as a whole. The error correction equation income elasticity is positive, indicating that SCL residential customers treat electricity as a normal good in the short-run.

Planning for new customers is a major concern for utility companies. Determining the increase in the number of customers is important in planning for the expansion of service, as new meters and distribution lines must be installed for new residencies. The number of customers is modeled as a function of population and lagged employment. The cointegrating equation results indicate that both population and employment affect the SCL customer base over the long-run. The error correction equation attributes short-run customer base changes to employment fluctuations rather than population, potentially reflecting the impacts of migration on the electricity grid.

Out-of-sample simulations indicate that forecasts generated with estimated equations are reasonable. Accordingly, long-run increases in personal income will potentially not translate into greater SCL load demands in the manner that has been reported for other electric utilities. That can help alleviate pressures to augment generation resources. Whether this holds for other metropolitan economies is not known, but recent empirical evidence points to a long-run negative correlation between household incomes and residential electricity usage. That, in combination with careful rate setting, may allow existing generation capacity to accommodate more regional economic expansion than might otherwise be expected.

ABSTRACT

There is a growing interest in reducing energy consumption and the associated greenhouse gas emissions in every sector of the economy. The residential sector is a substantial consumer of energy in every country, and therefore a focus for energy consumption efforts. Since the energy consumption characteristics of the residential sector are complex and inter-related, comprehensive models are needed to assess the technoeconomic impacts of adopting energy efficiency and renewable energy technologies suitable for residential applications.

The aim of this paper is to provide an up-to-date review of the various modeling techniques used for modeling residential sector energy consumption. Two distinct approaches are identified: top-down and bottom-up. The top-down approach treats the residential sector as an energy sink and is not concerned with individual end-uses. It utilizes historic aggregate energy values and regresses the energy consumption of the housing stock as a function of top-level variables such as macroeconomic indicators (e.g. gross domestic product, unemployment, and inflation), energy price, and general climate. The bottom-up approach extrapolates the estimated energy consumption of a representative set of individual houses to regional and national levels, and consists of two distinct methodologies: the statistical method and the engineering method.

Each technique relies on different levels of input information, different calculation or simulation techniques, and provides results with different applicability. A critical review of each technique, focusing on the strengths, shortcomings and purposes, is provided along with a review of models reported in the literature.

1. Introduction

Nationally, energy consumption of the residential sector accounts for 16–50% of that consumed by all sectors, and averages approximately 30% worldwide as shown in Fig. 1. This significant consumption level warrants a detailed understanding of the residential sector's consumption characteristics to prepare for and help guide the sector's energy consumption in an increasingly energy conscience world; conscience from standpoints of supply, efficient use, and effects of consumption. In response to climate change, high energy prices, and energy supply/demand, there is interest in understanding the detailed consumption characteristics of the residential sector in an effort to promote conservation, efficiency, technology implementation and energy source switching, such as to on-site renewable energy.

Energy consumption of other major sectors such as commercial, industrial, agriculture and transportation are better understood than the residential sector due to their more centralized ownership, self-interest and expertise in reducing energy consumption, and high levels of regulation and documentation. The residential sector is largely an undefined energy sink due to the following reasons:

- The sector encompasses a wide variety of structure sizes, geometries and thermal envelope materials.
- Occupant behaviour varies widely and can impact energy consumption by as much as 100% for a given dwelling [2].
- Privacy issues limit the successful collection or distribution of energy data related to individual households.
- Detailed sub-metering of household end-uses has prohibitive cost.

The residential sector consumes secondary energy. Secondary energy is that received in suitable form for use by the consuming systems to support the living standards of occupants. The major end-use groups of secondary energy are:

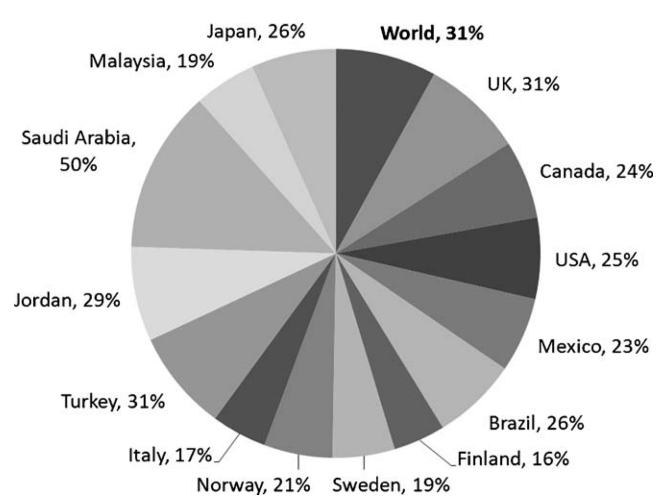

Fig. 1. Residential energy consumption shown as a percentage of national energy consumption and in relative international form [1].

- Space heating (SH) and space cooling (SC)—energy required to support thermal losses incurred across the building envelope due to conduction and radiation, as well as air infiltration/ventilation in an effort to maintain the living space at a comfortable temperature and air quality.
- Domestic hot water (DHW)—energy required to heat water to a comfortable or appropriate temperature for occupant and appliance uses.
- Appliances and lighting (AL)—energy consumed to operate common appliances (e.g. refrigerator and coffee maker) and for the provision of adequate lighting.

The degree to which these groups affect the overall energy consumption is highly dependent on climate, physical dwelling characteristics, appliance and system characteristics, ownership, and occupant behaviour.

The total energy consumption of a dwelling is that required to support all energy consuming end-uses, inclusive of the losses due to appliance and system efficiencies. The end-uses may have complex inter-related effects with regards to energy consumption. For example, the energy consumption of most common appliances results in heating of the conditioned living area. The energy consumption can be supplied by one or more secondary energy sources and includes on-site generation and passive solar gains. The sum of each dwelling's energy consumption for a given area (e.g. city and country) results in a regional or national residential sector energy consumption, the modeling of which is the topic of interest for this review.

Energy consumption modeling of buildings seeks to quantify energy requirements as a function of input parameters. Models may be used for a variety of reasons, the most common being the determination of regional or national energy supply requirements (macro-scale) and the change in energy consumption of a particular dwelling due to an upgrade or addition of technology (micro-scale). Modeling of this nature is useful as it can guide decisions of policy regarding the residential stock, both old and new. By quantifying the consumption and predicting the impact or savings due to retrofits and new materials and technology, decisions can be made to support energy supply, retrofit and technology incentives, new building code, or even demolition and re-construction.

Residential energy models may focus on a thermal zone, building, neighbourhood, city, state or province, region, or nation. The level of detail of input parameters is a function of data availability, model focus and purpose, and assumptions. Increased detail allows for a more comprehensive investigation of particulars, although accurate assumptions may significantly ease the modeling process and provide suitable results.

Emphasis of this review is placed on models that are or could be used to model the residential sector energy consumption. Energy consumption models of this scope involve an approximation of the residential stock and a methodology for estimating the energy consumption of the stock. Such models are useful to formulate policy decisions regarding the residential stock, both old and new. By quantifying the consumption and predicting the impact or savings due to construction/demolition, retrofits and new materials and technology, decisions can be made to support energy supply, retrofit and technology incentives, new building codes, or even demolition and re-construction. This review of residential sector energy consumption models introduces the modeling techniques, reviews the published literature and concludes with an analysis of the strengths and weaknesses of the techniques.

2. Objective

The objective of this paper is to provide an up-to-date review of the various modeling techniques used for modeling residential sector energy consumption. Two distinct approaches are identified: top-down and bottom-up. Each technique relies on different levels of input information, different calculation or simulation techniques, and provides results with different applicability. A critical review of each technique, focusing on the strengths, shortcomings and purposes, is provided along with a review of models reported in the literature.

3. Modeling methodologies

Residential energy models rely on input data from which to calculate or simulate energy consumption. The level of detail of the available input data can vary dramatically, resulting in the use of different modeling techniques which seek to take advantage of the available information. These different modeling techniques have different strengths, weaknesses, capability, and applicability.

3.1. Types and sources of information

Depending on the modeling methodology to be used, the input data required to develop residential energy models includes information on the physical characteristics of the dwellings, occupants and their appliances, historical energy consumption, climatic conditions, and macroeconomic indicators. The information can be collected independently or concurrently, can be national aggregate or individual dwelling values, and vary greatly in level of detail. The basic information collection method is by survey, the results of which are published in raw or analyzed form.

The preliminary estimate of the total residential sector energy consumption is usually published by governments which compile gross energy values submitted by energy providers (examples are Canada [3], USA [4], UK [5], and China [6]). These estimates provide indicators as to sector energy consumption but may be inaccurate as they do not account for unreported energy or on-site generation. A more detailed source of energy consumption data, typically on a monthly basis and for each dwelling, is the billing records of energy suppliers (e.g. monthly dwelling electricity bill). However, with no additional housing information these energy consumption values are difficult to correlate due to the wide variety of dwellings and occupants.

To provide more detailed information than the above aggregate values, housing surveys are conducted. These surveys target a sample of the population to determine building and occupant characteristics and appliance penetration levels (examples are Canada [7], USA [8], and UK [9]). The Tyndall Centre conducted a worldwide review of such surveys [10]. Surveys typically attempt to define the house geometry and thermal envelope, ownership of appliances, occupants and their use of appliances and preferred settings, and demographic characteristics. In addition, surveys may attempt to obtain the energy suppliers' billing data (described above) and alternative energy source information (e.g. unreported wood usage) to correlate the energy consumption of the house with its characteristics identified during the survey. This allows for calibration through reconciliation of a model's predicted energy consumption with actual energy billing data. This level of information is superior to the previously mentioned energy supplier values; however, it is limited due to collection difficulties and cost, and therefore it is imperative that the selected sample be highly representative of the population. Also, occupant descriptions of their appliance use are highly subjective and can be influenced by the season during which the survey takes place [7]. Examples of surveys which have been condensed for the purpose of energy simulation are [11,12].

Elimination of subjective appliance usage estimation is achieved by "sub-metering". This method places energy metering devices on the large energy consuming appliances within the household to determine both their component of the house energy consumption and their usage profile as a function of time (e.g. [13]). This level of information is rare due to its prohibitive cost.

Estimated total sector energy, individual billing data, surveys, and sub-metering have been used to varying degrees in the development of residential energy consumption models. The determination of which information is used depends on availability and model's purpose. The purpose of models ranges widely and may be directed towards determining supply requirements, price and income elasticity, and the energy consumption impacts of upgrades, technologies, or changes to behavioural patterns.

3.2. Techniques to model energy consumption

Techniques used to model residential energy consumption can broadly be grouped into two categories, ''top-down'' and ''bottom-up''. The terminology is with reference to the hierarchal position of data inputs as compared to the housing sector as a whole. Top-down models utilize the estimate of total residential sector energy consumption and other pertinent variables to *attribute* the energy consumption to characteristics of the entire housing sector. In contrast, bottom-up models *calculate* the energy consumption of individual or groups of houses and then extrapolate these results to represent the region or nation.

Groupings of top-down and bottom-up techniques for modeling residential energy consumption are shown in Fig. 2 and are discussed in the following sections.

3.2.1. Overview of the top-down approach

The top-down approach treats the residential sector as an energy sink and does not distinguish energy consumption due to individual end-uses. Top-down models determine the effect on energy consumption due to ongoing long-term changes or transitions within the residential sector, primarily for the purpose of determining supply requirements. Variables which are commonly used by top-down models include macroeconomic indicators (gross domestic product (GDP), employment rates, and price indices), climatic conditions, housing construction/demolition rates, and estimates of appliance ownership and number of units in the residential sector.

Fig. 2 shows two groups of top-down models: *econometric* and *technological*. Econometric models are based primarily on price (of, for example, energy and appliances) and income. Technological models attribute the energy consumption to broad characteristics of the entire housing stock such as appliance ownership trends. In addition there are models which utilize techniques from both groups.

Top-down models operate on an equilibrium framework which balances the historical energy consumption with that estimated based on input variables. The strengths of top-down modeling are the need for only aggregate data which are widely available, simplicity, and reliance on historic residential sector energy values which provide ''inertia'' to the model. As the housing sector rarely undergoes paradigm shifts (e.g. electrification and energy shocks), a weighted model provides good prediction capability for small deviations from the status quo. For example, if housing construction increased the number of units by 2%, an increase in total residential energy consumption of 1.5% might be estimated by the top-down model, as new houses are likely more energy efficient. If this construction was increased to 10% of the units the top-down model could have difficulty in producing an appropriate estimate as the vintage distribution of the housing stock would have changed significantly.

The reliance on historical data is also a drawback as top-down models have no inherent capability to model discontinuous advances in technology. Furthermore, the lack of detail regarding the energy consumption of individual end-uses eliminates the capability of identifying key areas for improvements for the reduction of energy consumption.

3.2.2. Overview of the bottom-up approach

The bottom-up approach encompasses all models which use input data from a hierarchal level less than that of the sector as a whole. Models can account for the energy consumption of individual end-uses, individual houses, or groups of houses and are then extrapolated to represent the region or nation based on the representative weight of the modeled sample. The variety of data inputs results in the groups and sub-groups of the bottom-up approach as shown in Fig. 2.

Statistical methods (SM) rely on historical information and types of regression analysis which are used to attribute dwelling energy consumption to particular end-uses. Once the relationships between end-uses and energy consumption have been established, the model can be used to estimate the energy consumption of dwellings representative of the residential stock. *Engineering* methods (EM) explicitly account for the energy consumption of end-uses based on power ratings and use of equipment and systems and/or heat transfer and thermodynamic relationships.

Common input data to bottom-up models include dwelling properties such as geometry, envelope fabric, equipment and appliances, climate properties, as well as indoor temperatures, occupancy schedules and equipment use. This high level of detail is a strength of bottom-up modeling and gives it the ability to model technological options. Bottom-up models have the capability of determining the energy consumption of each end-use and in doing so can identify areas for improvement. As energy consumption is calculated, the bottom-up approach has the capability of determining the total energy consumption of the residential

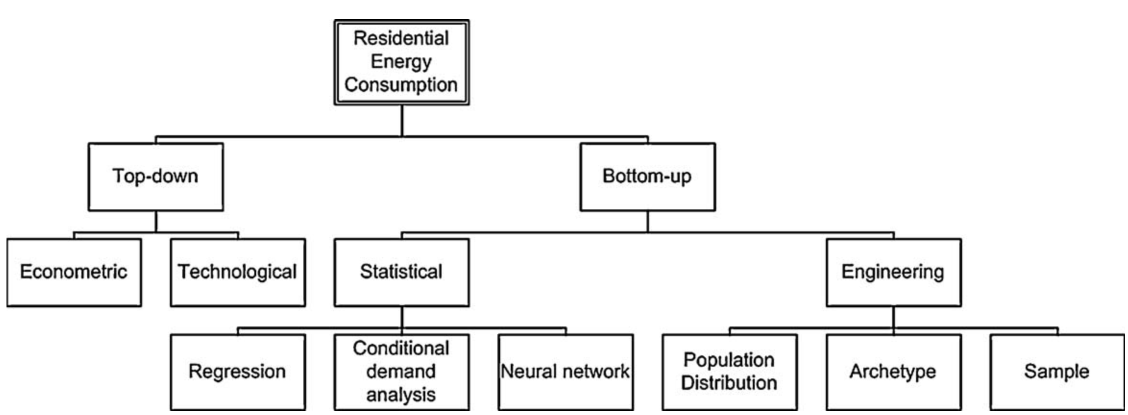

Fig. 2. Top-down and bottom-up modeling techniques for estimating the regional or national residential energy consumption.

sector without relying on historical data. The primary drawback caused by this level of detail is that the input data requirement is greater than that of top-down models and the calculation or simulation techniques of the bottom-up models can be complex.

In all cases the bottom-up models must be extrapolated to represent the housing sector. This is accomplished using a weighting for each modeled house or group of houses based on its representation of the sector.

A notable capability of the bottom-up approach is its ability to explicitly address the effect of occupant behaviour and "free energy" gains such as passive solar gains. Although free energy gains have historically been neglected during residential analysis, they are now a common design point as focus is placed on alternative energy technologies. Statistical methods attribute all of the *measured* energy consumption to end-uses and in doing so incorporate the occupant's behaviour with regards to use and settings of appliances. However, if all energy sources are not accounted for, the end-use energy consumption estimates are derated by this consumption difference. Based in its physical principle roots, the EM has the ability to capture the additional energy consumption level based on requirements, inclusive of free energy. However, occupant behaviour must be estimated which is difficult as behaviour has been shown to vary widely and in unpredictable ways.

The following sections examine the modeling techniques by reviewing published models. The applicability, basic methodology and major conclusions found by the researchers are listed. There is a tendency towards chronological order to facilitate understanding of the modeling technique development stream and contributions by the authors. Certain techniques were found to follow a clear development stream (e.g. conditional demand analysis) while others contain a wide variety of techniques and are discontinuous. Emphasis is placed on modeling technique development and less on the simple application to a new region.

4. Top-down models

The use and development of the top-down modeling approach proliferated with the energy crisis of the late 1970s. In an effort to understand consumer behaviour with changing supply and pricing, broad econometric models were developed for national energy planning. These models require little detail of the actual consumption processes. The models treat the residential sector as an energy sink and regress or apply factors that affect consumption to determine trends. Most top-down models rely on similar statistical data and economic theory.

As the housing stock in most regions is continuously undergoing improvement and increase, simply modeling the energy consumption solely as a function of economic variables is short-termed. Hirst et al. [14] initiated an annual housing energy model of the USA. Their model relied on econometric variables and included a component for growth/contraction of the housing stock. Their work was expanded and improved over the following years resulting in an econometric model which had both housing and technology components [15,16]. The housing component evaluates the number of houses based on census data, housing attrition and new construction. The technology component increases or decreases the energy intensiveness of the appliances as a function of capital cost. The economic component evaluates changes in consumption based on expected behavioural changes and efficiency upgrades made to the technology component. Finally, market penetration is considered a function of income and demand/supply. The simulation model combines the changes in outputs of the components and estimates the energy consumption given historic energy consumption values. The authors felt their model was sensitive to major demographic, economic and technological factors, but recognized the need to continually update all assumed information to improve quality.

Saha and Stephenson [17] developed a similar model for New Zealand although it had a technological focus. Their economic and housing components drive separate analysis of SH, DHW, and cooking, and are added to obtain total consumption. Their basic energy balance, as shown in Eq. (1), determines the annual energy consumption of each fuel used to support each end-use group as a function of stock, ownership, appliance ratings and use. Using historical data, their prediction capability was excellent throughout the 1960s and 1970s although there is significant divergence toward the latter half of the 1970s. This may be due to the model not accounting for shifts in home insulation levels

$$E_{\mathrm{an},e,f} = S \cdot C_{e,f} \cdot R_{e,f} \cdot U_{e,f} \quad (1)$$

where E is the annual energy consumption of end-use group e, corresponding to fuel type, f, S is the level of applicable housing stock, C is the appliance ownership level, R is the rating of all appliances within an end-use group, and U is a use factor.

Haas and Schipper [18] recognized that energy consumption of the housing stock is poorly modeled by only a few econometric indicators. They identified "irreversible improvements in technical efficiency" which are a result of consumer response that not only reduces energy consumption due to rising price, but responds by making upgrades to their dwelling. Consequently a subsequent reduction in price would not cause a perfectly elastic rebound. To quantify this asymmetrical elasticity, they developed econometric models for the USA, Japan, Sweden, West Germany and the UK based on the time periods of: 1970–1993, 1970–1982, and 1982–1983. They found very flat (nearly zero) rebound of energy consumption after periods of increased price, suggesting the typical price elasticity is a diluted average. They also state saturation of appliances can lead to reduced income elasticity and they found limited correlation between increasing technological efficiency leading to increased energy use. When the authors included technological energy intensity in their model (using a bottom up approach based on individual appliance ratings) they found reduced error and that the irreversible share of price elasticity became hidden in the coefficient of intensity.

Two tier econometric models that evaluate choice of system (discrete) and utilization (continuous) are common. Nesbakken [19] developed such a model for Norway, testing sensitivity and stability across a range of income and pricing. The author considered three years of expenditure surveys and energy consumption to determine differences along the time dimension. Their findings were consistent with negative price elasticity and maximization of utility. Different income groups resulted in similar findings although the responses were slightly higher for higher income groups.

Bentzen and Engsted [20] revived simple economic modeling of residential energy consumption. They tested the following three annual energy consumption regression models for Denmark:

$$E_{\mathrm{an},t} = b + c_1 E_{\mathrm{an},t-1} + c_2 I_{\mathrm{disp},t} + c_3 Pc_t \quad (2)$$

$$E_{\mathrm{an},t} = b + c_1 E_{\mathrm{an},t-1} + c_2 I_{\mathrm{disp},t} + c_3 Pc_t + c_4 HDD_t \quad (3)$$

$$E_{\mathrm{an},t} = b + c_1 E_{\mathrm{an},t-1} + c_2 I_{\mathrm{disp},t} + c_3 Pc_t + c_4 HDD_t + c_5 Pc_{t-1} \quad (4)$$

where E is the annual energy consumption for year, t, I is the disposable household income, Pc is the price of energy, HDD is the heating degree days, b is a constant, and c are coefficients.

From 36 years of data they found that, in all three cases, long-term energy consumption was strongly affected by income and lagged energy consumption, and lagged pricing trumped current

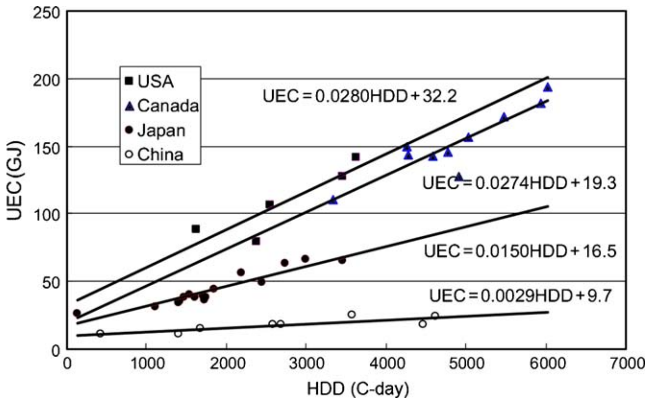

Fig. 3. Comparison of National UEC values [21].

pricing. Their findings indicate that future energy price must increase with income to maintain the current consumption level.

Using aggregate national residential energy values, Zhang [21] compared international values of unit energy consumption (UEC) to determine to potential changes in the sector's energy consumption. The author calculated the UEC for various regions of China based on energy consumption and the number of residences, and compared the Chinese UEC with those of other countries. The results indicate that when normalized for heating requirements based on climate (i.e. heating degree days (HDD)), Japan uses approximately half the UEC of the USA and Canada, as shown in Fig. 3. This may be attributed in part to the high ratio of apartment buildings in Japan (40%). China is closer to one quarter of the North American UEC, owing to limited adoption of space heating devices. The paper also discusses the potential of the Chinese residential sector following the North American or Japanese energy consumption characteristics. Interestingly, the model identified that although China is growing, the secondary energy consumption of the residential sector has remained constant due to switching away from coal as a fuel.

Ozturk et al. [22] and Canyurt et al. [23] proposed the use of genetic algorithms (GA) to determine the relationships between Turkish residential–commercial energy consumption and the following: GDP, population, import/export, house production, cement production and appliance sales. GA models utilize concepts of biology and Darwin's theory of survival of the fittest. Initiated chromosomes (potential solutions) are assessed on the basis of fit (sum of squared errors) to determine their level of participation. Chromosomes are crossed to exchange potential solution characteristics (coefficients of input variables) with the potential of mutations to account for solutions which were not part of the initial population. The authors' GA model estimates the coefficients of the linear model based on the aforementioned variables and their combinations. The resultant model had excellent fit with the calibration information and their projections through the year 2020 were similar to other models. They note the benefits of the GA as requiring limited information and easy development.

The national energy modeling system (NEMS) incorporates a current econometric energy model of the USA housing stock [24]. The model is used for mid-term forecasting and policy analysis. It includes five components: housing stock forecast, technology, appliance stock forecast, building shell integrity, and distributed generation equipment. The appliance stock component places emphasis on appliance lifetime and saturation levels, functions which have been studied in depth for Canada by Young [25]. The distributed generation component indicates that emphasis is being placed on the integration of non-traditional energy sources; it looks at system cost, efficiency, penetration parameters, and solar insolation levels. The calculated energy consumption is then fed back into the NEMS for use with other models and overall energy supply prediction.

Using the entire building register of Goteborg (68,200 buildings) and energy data from the largest energy supplier, Tornber and Thuvander [26] developed an energy model of the building stock. The energy data was measured at metering stations, and was distributed among connected buildings on the basis of building use and age. The model utilizes geographical information systems (GIS) to visually assist the assessment of the consumption rates of different energy sources throughout Goteborg. Although they were unable to directly link the energy consumption to individual buildings, their spatial model clearly identifies energy use within groups of buildings and may be used for identification of high consumption areas.

Labandeira et al. [27] extended a regression model by developing a six equation demand model of Spanish residential energy consumption. Separate equations were developed for energy consumption associated with: electricity, natural gas, propane, automotive fuel, public transport, and food. They found that these products are price inelastic. They regressed the energy consumption of over 27,000 houses as a function of demographic, macroeconomic, and climate variables. They experienced reduced multicollinearity problems as their dataset covered an extended period of time (changing appliances ownership) and this also provided longer-term elasticity assessment.

Siller et al. [28] created a model of the Swiss residential sector to test the impacts of renovations and new construction in an attempt to achieve energy consumption and greenhouse gas emissions targets. Their model is based on the effective reference area which is a measure of the effective heated area and is calculated based on census data. They developed modeling matrices which account for the renovation of buildings and if demand is met, new construction of buildings. In calculating energy consumption they use building type, energy standards, efficiency, and heat demand per area. The update of the housing stock is through new construction and renovation, of which the latter is only occasionally realized. They point out that these estimates have a strong affect on model uncertainty.

Balaras et al. [29] constructed a renovation model of the Hellenic housing stock. Using an assessment of the housing stock and current energy consumption figures, they estimated the impact of fourteen different energy conservation measures that were applied to houses in need of refurbishment. They found the housing stock lacking in insulation and predicted that adding insulation to the stock would save 49% of current space heating energy consumption.

5. Bottom-up models

The bottom-up approach was developed to identify the contribution of each end-use towards the aggregate energy consumption value of the residential stock. This refines the understanding of the details associated with the energy consumption.

There are two distinct categories used in the bottom-up approach to evaluate the energy consumption of particular end-uses. The SM utilizes dwelling energy consumption values from a sample of houses and one of a variety of *techniques* to regress the relationships between the end-uses and the energy consumption. SM models can utilize macroeconomic, energy price and income, and other regional or national indicators, thereby gaining the strengths of the top-down approach. The EM relies on information of the dwelling characteristics and end-uses themselves to calculate the energy consumption based on power ratings and use characteristics and/or heat transfer and thermodynamic principles. Consequently, the engineering technique has strengths such as the ability to model new technologies based solely on their traits. Once developed, the bottom-up models may be used to estimate the energy consumption of houses representative of the residential stock and then these results can be extrapolated to be representative of the regional or national residential sector.

5.1. Statistical techniques

The vast quantity of customer energy billing information stored at the major energy suppliers worldwide is an unprecedented data source for energy modeling. Researchers have applied a variety of SM techniques to utilize this and other information to regress the energy consumption as a function of house characteristics. A capability of the SM techniques is their ability to discern the effect of occupant behaviour. This is of benefit to residential modeling as occupant behaviour has been found to range widely and is poorly represented by simplified estimates [2,30,31].

The three well-documented techniques, all of which use a sample of houses, are:

- Regression—The regression technique uses regression analysis to determine the coefficients of the model corresponding to the input parameters. These models regress the aggregate dwelling energy consumption onto parameters or combinations of parameters which are expected to affect energy consumption. The model is evaluated based on goodness of fit. Input variables which are determined to have a negligible effect are removed for simplicity. Based on the combinations of inputs, the model's coefficients may or may not have physical significance.
- Conditional demand analysis (CDA)—The CDA method performs regression based on the presence of end-use appliances. By regressing total dwelling energy consumption onto the list of owned appliances which are indicated as a binary or count variable, the determined coefficients represent the use level and rating. The primary strength of this technique is the ease of obtaining the required input information: a simple appliance survey from the occupant and energy billing data from the energy supplier. However, it does require a dataset with a variety of appliance ownership throughout the sample. This technique exploits the differences in ownership to determine each appliance's component of the total dwelling energy consumption. In order for the CDA technique to produce reliable results, and depending on the number of variables used, data from hundreds or even thousands of dwellings are required.
- Neural network (NN)—The NN technique utilizes a simplified mathematical model based on the densely interconnected parallel structure of biological neural networks. The technique allows all end-uses to affect one another through a series of parallel "neurons". Each neuron has a bias term and array of coefficients that are multiplied by the value of the preceding layer's neurons. Similar to regression models it seeks to minimize error and may apply scaling and activation functions to account for non-linearity. As it is a parallel model, the coefficients have no physical significance.

5.1.1. Regression

In an effort to identify unusual metering occurrences (e.g. broken meter) and evaluate the level of households with more than one energy source for space heating, Hirst et al. [32] used the Princeton scorekeeping model with monthly or bimonthly energy supplier billing data. They examined the weather and non-weather sensitive elements of the household energy consumption of dwellings by regressing the energy billing data onto a non-weather dependent constant and a weather dependent coefficient based on HDD, as shown in Eq. (5). They left the reference temperature for determination of the HDD as a variable, to be adjusted between 4 °C and 24 °C in an effort to reduce error and increase the multiple correlation coefficient (R^2). The adjustment of T_{ref} was shown to be effective by Jones and Harp [33] who reduced it from the accepted value of 18.0–16.9 °C and achieved more representative results for the space heating requirements of Oklahoma

$$E_{\text{an},t} = b + c\ \text{HDD}_t(T_{\text{ref}}) \tag{5}$$

where E is the annual energy billing data from period, t, HDD is the heating degree days with reference temperature, T_{ref}, b is constant, and c is a coefficient.

The coefficients in the above model were termed "fingerprints" and directed towards determining unusual metering occurrences and identifying the use of alternative space heating fuels when comparing the monthly measured house energy consumption to that predicted by the model. Recently, a similar analysis was conducted by Raffio et al. [34] with the goal of identifying energy conservation potential within a regional area. A similar model with "energy signature" coefficients was developed. These coefficients were compared regionally and also evaluated over the course of the seasons for the identification of patterns which can be used to assess potential energy conserving changes. The authors give examples such as the application of DHW conserving devices to dwellings with high non-weather dependent energy consumption and the application of programmable thermostats to high balance point T_{ref} buildings. While the model cannot determine the impact of these changes, it may identify the potential for application. The primary advantages of this model are simplicity, only requiring billing data, and the capability of normalized comparison across many different residences using a sliding scale which is continuously updated from new billing data. Utilizing larger sets of billing data, the models can become descriptive of a nation.

Tonn and White [35] developed a regression model with four simultaneous equations: separate equations of electricity use associated with SH and AL, wood use, and indoor temperature. Data was sourced from 100 sub-metered homes that utilized wood heat. In an attempt to encompass occupant behaviour they conducted an extensive survey (300 questions) which asked questions related to goals and motivations, and occupants self-defined socioeconomic response. Their desire was to determine the motivation or ethical considerations in energy use. They developed 30 different regression models, consecutively eliminating variables with insignificant impact. Their four regression equations achieved R^2 values ranging from 0.80 to 0.91. While housing characteristics played a distinct role in the models, they found ethical motivations outweigh economic motivations. They found education level and age of the head of household not to affect any of the four equations.Douthitt [36] constructed a model of residential space heating fuel use in Canada by regressing consumption as a function of present and historic fuel price, substitute fuel price, total fuel consumption, and a vector of building structure, climatic, and occupant characteristics. Using 370 records, they achieved R^2 values equal to 0.52 (natural gas), 0.76 (heating oil), 0.37 (electricity with natural gas available), and 0.79 (electricity with no natural gas available). The author found that the sample with energy source alternatives achieve near unity price elasticity, the implication being towards fuel subsidies being ineffective at reducing annual fuel cost per house. Income elasticity was also very unitary, indicating that providing subsidies (in effect income) to low-income families would result in increased usage.

Fung et al. [37] adopted the regression techniques of [36] and others to determine the impact on Canadian residential energy consumption due to energy price, demographics, and weather and equipment characteristics. They found both short and long term fuel price elasticity to be negative, although the long term was larger in magnitude. Income elasticity was found to be insignificant. These results were similar for each end-use group (i.e. SH/SC, DHW, and AL).

5.1.2. Conditional demand analysis

Parti and Parti [38] developed the CDA method given the availability of a detailed survey of appliance and occupants of over 5000 households and their corresponding monthly electrical billing data from the electricity utility in San Diego. They recognized the limitations inherent to an engineering model that approximates occupant behaviour based on theoretical considerations and therefore they attempted to determine the use level of individual appliance based on regression methods. They proposed a *conditional demand regression equation* based on the indication of appliance ownership and expected relations with other house characteristics such as floor area or demographic factors gathered from a survey.

Their regression equation, one for each month of a year of billing data, take the form

$$E_{\text{mo}} = \sum_{i}\sum_{app} c_{app,i}(V_i C_{app}) \tag{6}$$

where E is the monthly electrical energy consumption, C is a variable indicating appliance presence or count for appliances, *app*, V is a set of interaction variables with elements, i, such as the number of occupants, income, and floor area, and c is a coefficient.

The appliance at *app* = 0 is unspecified to account for appliances whose presence were not explicitly surveyed and the interaction variable when $i = 0$ accounts for appliance energy consumption unrelated to interactions with other surveyed information.

The authors specified conditions to limit use of the significant appliances to help in regression coefficient determination. These included disallowing air conditioning from November through March and space heating from July through August. They considered the dominant electrical end-uses: air conditioning, space heating, water heating, and common appliances which include dishwasher, cooking range, dryer, and refrigerators and freezers. The interaction variables corresponding to end-use groups are shown in Table 1.

The final model coefficients were indicative of appliance use and resulted in R^2 values ranging from 0.58 to 0.65. As the regression model included demographic variables, the authors were able to determine econometric effects such as income and energy price elasticity. In comparison with engineering estimates, their CDA model under predicts energy consumption of space heating and over predicts energy consumption of water heating and common appliances. The authors believe they could incorporate solar technologies, but recognize the need for sufficient samples and associated annual dwelling energy consumption data. They see the benefits of the CDA method including the disaggregation of energy consumption by end-use without sub-metering and the inclusion of behavioural aspects within the coefficients.

Using 15 min interval load data from 100 Los Angeles electricity customers, Aigner et al. [39] utilized the CDA method to determine hourly regression equations. Based on constant appliance dummy variables, they found the regression resulted in inadequate coefficients. For example, the magnitude of coefficients (indicating use level) changed throughout the day with load level, but the relationship between different appliances did not, indicating that the coefficients represent an average use level and are not indicative of the daily use profile. To promote differences in the coefficients, the authors imposed restrictive windows of appliance use; specifically, laundry and cooking devices were excluded over the period of 2–5AM. Their results compared to actual occupant load profiles better than conventional CDA.

Caves et al. [40] developed a CDA model of the residential electricity energy consumption of Los Angeles customers by incorporating prior information through the use of Bayesian inference in an effort to reduce unreasonable or negative coefficients estimated by the conventional CDA method. The prior information was developed by using the EM to model appliances and systems and estimate load profiles. These profiles were used to calculate coefficients of use, similar to the CDA coefficients. A typical CDA model, based on a sample of 129 houses with daily energy consumption information (excluding weekends) for the summertime in Los Angeles was constructed using a method similar to [38]. Given the confidence levels of the EM coefficients and the CDA method coefficients, these weighted values are combined using Bayesian techniques to estimate final coefficients of the CDA regression model. This combination approach reduces the multicollinearity effects which can result in negative or unreasonable coefficients; however, it relies on engineering estimates of occupant behaviour.

Bartels and Fiebig propose an alternative method that incorporates sub-metered end-use energy consumption of a subset of the sample into the CDA model [41,42]. This was accomplished by removing the energy consumption and independent variables of the measured appliances within the sub-metered subset of houses. In doing this, they reduced the regression requirements of the subset and weighted the regression of the coefficients of the remaining sample. One advantage of this method is that the elimination of certain end-use consumption of the sub-metered subset increases the resolution and therefore the confidence level of the estimates of non-metered appliances. This is an improvement over using the EM to determine estimates of certain end-uses based on occupant behaviour.

LaFrance and Perron [43] furthered the CDA method by incorporating energy consumption data from three different years over a decade for Quebec. This allowed for the determination of changes in annual energy consumption as a function of changing appliance stock (specifically the addition of electric space heat), and long term pricing response. The database they used was significantly larger than previous efforts, approximately 100,000 samples in total, and contained additional information such as weather relations (heating and cooling degree days), cords of wood (an important energy source for space heating in Quebec), water heater characteristics and certain demographics. These qualities increased the R^2 coefficient to a range of 0.55–0.70.

Their CDA model for each year of available data allowed them to identify changing ownership which evolved to larger, more

Table 1
Interaction variables which have an effect on the energy consumption of particular appliances or equipment [38].

Appliances and equipment	Interaction variables				
	Number of occupants	Electricity price	Household income	Floor area	Heating/cooling per unit area
Common appliances	✓	✓	✓		
Refrigerator	✓				
Hot water	✓	✓	✓		
Space heating and cooling		✓	✓	✓	✓

consuming appliances throughout the period. Strong relationships were identified between incentive activities and appliance penetration. They found the CDA method could estimate the space heating energy consumption associated with wood as an energy source better than engineering estimates. This is due to direct occupant control over wood burning devices (e.g. damper control) and also the wide range of efficiency during operation. The authors identify a multicollinearity issue, the inability to determine which of two or more near linear related independent variables are having an impact on the dependent variable (energy consumption). They found that the nearly ubiquitous presence of the refrigerator and small unspecified appliances made it difficult to determine their impacts. They suggest improving the estimation by further distinguishing certain appliances by their characteristics (e.g. age, size, and number of doors of a refrigerator). Furthermore, they identify that the net energy consumption of the households, as determined by billing data, is not inclusive of passive energy gains and therefore is not representative of the actual consumption of the house, only the net measured consumption. However, this does not impede the relative comparison of two appliances as the passive gains remain identical.

Hsiao et al. [44] combined the work of [40] and [41] by utilizing sub-metered end-use energy consumption as the Bayesian inference prior information. The approach used a small set (49 households) of direct metered end-use data and a larger set which included billing and survey information from Ontario Hydro customers (347 households). The prior information is formed from the mean and variance of the end-use data, thereby providing values which incorporate behavioural aspects better than simple EM estimation.

Bartels and Fiebig [45] further improved upon this modeling technique development stream by increasing "efficiency" of sub-metering by conducting a review of the house appliance survey prior to the sub-metering measurement. They identified houses which would contribute the most to the model by being sub-metered. Based on a preliminary review of 1901 house appliance surveys the authors chose 250 appropriate houses and certain appliances to sub-meter. Sub-metering was also focused on freezers and lighting, areas which posed significant difficulty due to multicollinearity in all previous CDA efforts. Given excellent sub-metered data they attempted to extend their annual model to a half-hour model (48 CDA equations per day); however this resulted in a drop in the R^2 values from 0.66 to 0.34.

Lins et al. [46] developed a national CDA model for Brazil featuring 10,818 dwellings based on monthly energy consumption. As the model covered a wide north-south geographical area with varying climatic conditions, they found it difficult to obtain R^2 greater than 0.5.

Aydinalp-Koksal and Ugursal [47] constructed a national residential CDA model based on over 8000 records from a 1993 Canadian national residential energy consumption survey [48]. To be applicable to the entire energy consumption of the Canadian residential sector, the authors developed three CDA models corresponding to the dominant energy sources in Canada: electricity, natural gas, and oil. As the survey data was highly detailed, new descriptive variables were added to the CDA equations including: programmable thermostats, heat recovery ventilation, heating equipment efficiency, windows and doors, aerators and laundry loads. They mention that the number of independent variables should be limited to facilitate regression and reduce poor approximations of smaller appliances which may be indistinguishable.

The three CDA models achieved R^2 values ranging from 0.79 to 0.89 which may be a result of their annual model that averages the daily and seasonal effects. Certain end-uses were under or overestimated similar to [38]. The authors examined socio-economic effects using the model. The effects were linear, which caused concern as the model was driven to extremity values such as one occupant. Interestingly, the presence of children and adults equivalently affected the electricity consumption of common appliances, lighting, and space cooling. The CDA models were compared to detailed NN and EM models conducted on the same database. The CDA method always under predicted the NN model, and under predicted the EM in the AL, cooling, and SH categories, but not the DHW category. The authors note that the CDA model coefficients are more transparent and their implications better understood in comparison with the NN method.

5.1.3. Neural network

The use of NN methods in modeling residential energy consumption has historically been limited, possibly due to the computational and data requirements or the lack of physical significance of the coefficients relating dwelling characteristics to total energy consumption. Because of their ability to capture non-linear characteristics, NN models have been used to forecast the varying electrical loads seen by utilities. Aydinalp et al. [49] provides a review of the literature and discusses the development of NN models for electrical load forecasting purposes, stating that hundreds of models have been developed. They further report that modeling of energy consumption of individual buildings using NN originated and evolved throughout the 1990s beginning with commercial buildings and progressing in complexity. Specifically noted is an hourly building energy simulation contest reported by Kreider and Haberl [50] in which the top contenders used "connectionist" methods (e.g. NN).

A simplified NN is shown in Fig. 4. Interconnectivity between each characteristic is found at hidden neurons. Coefficients for each input to a hidden or output neuron are included in respective vectors "$\bar{V}$". The neurons are also biased by the term "*b*". For a particular NN arrangement (3:2:1 shown in the figure) and appropriate scaling and activation functions, the coefficient vector and bias are adjusted using a variety of techniques to minimize error of the model. Once the values are determined, the model can be used calculate the energy consumption as a function of different inputs.

Issa et al. [51] introduced the application of NN modeling to the residential energy consumption of a region. They described the development of a NN model that uses energy performance index (EPI) and conditioned floor areas of a group of dwellings with billing data. The EPI is an assigned energy efficiency rating based on housing components. Their NN model bridged the gap between actual energy consumption and the EPI rating. No results were declared.

Mihalakakou et al. [52] created an energy model of a house in Greece using the NN methodology based on atmospheric conditions. Inputs included air temperature and solar radiation and the NN was trained using five years of hourly energy consumption

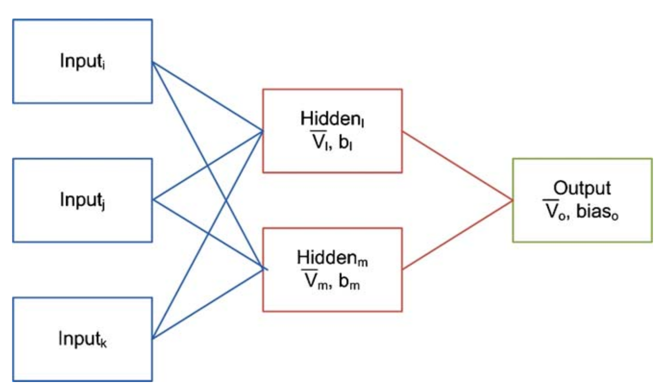

Fig. 4. Simplified NN with three inputs, two hidden neurons with coefficient arrays "$\bar{V}$" and bias "*b*", and one output.

data. Results of predicted energy consumption for the dwelling were excellent on an hourly basis. This can be attributed to the unprecedented amount of hourly "training" data used to calibrate the model. Sadly, while multiyear data was available, dates were not indicated as an input to the NN and therefore annual changes were not accounted for. This method may be extrapolated on a monthly basis using energy supplier billing data to a region of houses. It would therefore become a tool to estimate the variation in energy consumption between cold or warm years.

Aydinalp et al. [49,53] introduced a comprehensive national residential energy consumption model using the NN methodology. They divided it into three separate models: appliances, lighting and cooling (ALC); DHW; and SH. To differentiate the electrical energy consumption for ALC from DHW and SH, only houses which used natural gas or oil for heating loads were used to train the ALC model. The NN models used the 1993 Canadian national residential energy consumption survey [48].

The ALC NN model utilized appliance and heating system information, as well as demographic information for a total of 55 inputs. They trained the model using the annual ALC electricity consumption billing data and inputs from a 741 household "training dataset". The network was optimized by varying properties such as learning algorithm, scaling interval, and hidden layers, which were evaluated by maximizing the R^2 values. Once the network properties were determined it took 182 training cycles to achieve the final nodal coefficients and bias values.

A "testing set" of 247 houses was used to compare the ALC NN model with the EM. Prediction capabilities of the NN surpassed that of the EM, with R^2 values of 0.91 and 0.78, respectively when compared to the metered energy consumption. The authors commented on the ability of the NN to determine an individual appliance's component of the aggregate energy consumption by simply removing its presence from the modeled house. Appliance values compared well with other studies, but were not compared to sub-metered data. Specifically, the refrigerator consumption was not found to be rational, indicating an appliance saturation issue similar to that of the CDA method. As demographic factors were included as inputs, socioeconomic response was analyzed. It was found that ALC energy consumption increased as a second order polynomial as a function of household income.

Aydinalp et al. [54] extended the NN methodology from ALC loads of the Canadian residential sector to loads due to SH and DHW. This was accomplished using similar methods to those described above, using the remaining dataset that contained alternative energy sources. The ALC NN was also used to remove the ALC component when solving for SH and DHW provided by electricity sources. Values of R^2 were again higher than corresponding EM models based on the same data; however, Fig. 5 shows the SH energy consumption predicted by the NN has a biased error. A socioeconomic analysis was conducted and both SH and DHW energy consumption were found to vary linearly with income.

Yang et al. [55] presented a technique for an "adaptive" NN which functions by accumulating additional energy data or using a sliding window of recent energy data. This extends upon the static predictions made by conventional NN, and allows for the coefficients and bias to be updated as new information becomes available. They found that given a previously trained network, the updating of the coefficient and bias values to represent new data takes less time as the initial values are close to the final state. This technique could be applied for continuous update, similar to that of the top-down technique used by the USA EIA [24].

5.2. Engineering method

The EM accounts for energy consumption of the end-uses based on their ratings or characteristics. The EM is the only method that

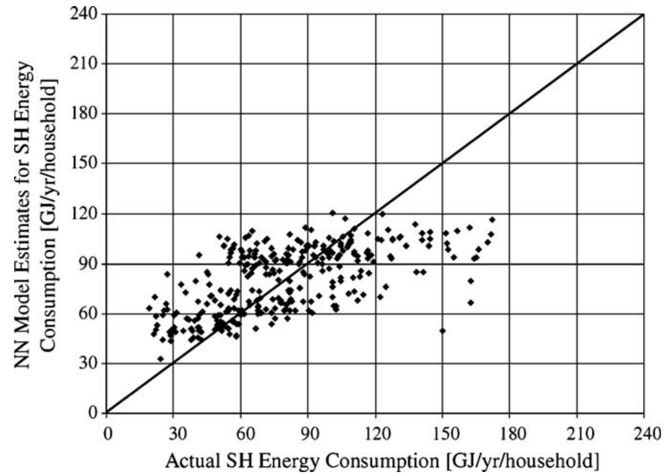

Fig. 5. Comparison of SH energy consumption using the NN technique to actual SH energy consumption [54].

can fully develop the energy consumption of the sector without any historical energy consumption information. Models can be as simple as an estimate of SH based on the climate through the use of HDD or as detailed as a complete thermodynamic and heat transfer analysis on all end-uses within the dwelling. As it functions based on the physics of the end-uses, the EM has the highest degree of flexibility and capability with regard to modeling new technologies which have no historical consumption data. However, occupant behaviour must be assumed. As occupant behaviour varies widely, this is difficult to estimate. Three EM techniques are identified in this review:

- Distributions—This technique utilizes distributions of appliance ownership and use with common appliance ratings to calculate the energy consumption of each end-use. As end-uses are typically calculated separately, this technique does not account for interactions amongst end-uses. The product of appliance ownership, appliance use, appliance rating and the inverse of appliance efficiency results in the energy consumption. By aggregating the appliance consumptions on a regional or national scale the residential energy consumption is estimated.
- Archetypes—This technique is used to broadly classify the housing stock according to vintage, size, house type, etcetera. It is possible to develop archetype definitions for each major class of house and utilize these descriptions as the input data for energy modeling. The energy consumption estimates of modeled archetypes are scaled up to be representative of the regional or national housing stock by multiplying the results by the number of houses which fit the description of each archetype.
- Sample—This technique refers to the use of actual sample house data as the input information to the model. This allows for the capture of the wide variety of houses within the stock and can be used to identify regions with high-energy consumption. If the sample is representative of the regional or national housing stock, the stock energy consumption can be estimated by applying appropriate weightings to the results. As the variety of houses varies widely, this technique requires a large database of representative dwellings.

5.2.1. Distributions

EM models can be constructed by using regional or national distributions of appliance ownership and use, and determining the end-use energy consumption. While they rely on national assessments of appliance penetration and can incorporate historic energy consumption, their level of disaggregation (by end-use) allows them to be considered bottom-up. As the number of houses and appliance penetration distributions are known, the resultant energy consumption is considered to be representative of the region or nation.Capaso et al. [56] developed an appliance use profile of the Italian residential sector based on distributions determined from housing surveys. Demographic and lifestyle data combined with engineering data of a wide range of appliances was used to calculate total house energy consumption. Their model was applied to the region and compared well with load recordings.

Jaccard and Baille [57] developed a model of Canadian provinces using the INSTRUM-R simulation tool. The inputs to the model include historic energy consumption, price, behavioural parameters, distribution levels of technologies, and quantification of appliance unit energy consumption, cost, and availability. The simulation tool then explicitly models the energy consumption of each appliance, the sum of which is considered to be the residential energy consumption. Functions are included to retire old housing stock and also to test the housing stock for retrofit potential. Based on the potential it simulates the purchase of new appliances. The authors detail the advanced life cycle cost assessment features of the model which do not assume perfect knowledge across space and time, thereby limiting a single technology capturing 100% of the market. They consider this to be a strong asset of the model as it more appropriately simulates the regional technology choices.

Using a combination of distributions and micro-level data sources, Kadian et al. [58] developed an energy consumption model of the residential sector of Delhi. They used a simplified end-use consumption equation to incorporate the penetration and use factors of all households, similar to Eq. (1) although extended to individual end-uses. They included end-uses such as lighting, water heating, air conditioning, refrigeration, cooking, washing, and certain subjective loads. The sum of the end-use energy consumption was input into the long range energy alternatives planning (LEAP) system to incorporate variables such as population, income, and increasing number of houses.

Saidur et al. [1] created a non-space heat residential energy model of Malaysia based on different researchers' distribution estimates of appliance ownership, appliance power rating and efficiency, and appliance use (there is no SH requirement in Malaysia). Their estimate of national annual energy consumption is the summation of the product of each appliance's variables and reciprocal of efficiency. Furthermore, they conducted an exergy analysis to complement their efficiency analysis. The exergy analysis allowed for a comparative tool by which to gauge different energy sources and conversion devices based on a reference state. They found an overall energy efficiency of 69% and exergy efficiency of 30% for Malaysia, as shown in Table 2. They state the gap in efficiencies is due to a mismatch of input and output quality levels (i.e. high temperature energy resources were used for low temperature applications). This is dominated by the refrigerator and air conditioner.

Table 2
Overall energy and exergy efficiency of the residential sector [1].

Country	Year	Overall energy eff.	Overall exergy eff.
China	2005	–	10
Canada	1986	50	15
USA	1970	50	14
Brazil	2001	35	23
Italy	1990	–	2
Japan	1985	–	3
Sweden	1994	–	13
Turkey	2004–2005	81	22
Norway	2000	–	12
Saudi Arabia	2004	76	9
Malaysia	2004	70	29

5.2.2. Archetypes

The EM can be applied to a limited set of dwellings that represent classes of houses found in the residential sector, commonly referred to as "archetypes". Depending on the level of detail, modeling of archetypes can capture the interconnectivity of appliances and end-uses within the house which is not possible using models based on distributions. Parekh [59] describes the process of developing archetypes for energy simulation. The author outlines three basic criteria in generating archetypes: geometric characteristics, thermal characteristics, and operating parameters. Using housing surveys and available housing data, geometric and thermal characteristics are correlated to arrive at various groupings found within the housing stock. Data from these archetype groups was examined for minimum, average, and maximum values for use in determining representative characteristics of each archetype for use with building simulation programs.

As the archetype modeling method typically involves a highly detailed integrated simulation of a house, its development progressed with computer and software capabilities. As the number of archetypes is limited, they are the input of choice for EM models as they reduce simulation time as compared with the sample technique which models each house within a database.

MacGregor et al. [60] developed the Nova Scotia residential energy model using three insulation/infiltration levels and nine dwelling types, resulting in 27 archetypes. They used typical values of occupancy, appliances and lights, and evaluated the energy consumption of each archetype using the hourly analysis program (HAP) developed by Carrier Corporation [61]. Energy consumption values were extrapolated to provincial levels based on the estimated number of dwellings represented by each archetype. The results were found to be in agreement with regional top down estimates. The model was used to evaluate the potential for energy savings and economic benefits of introducing small-scale fluidized-bed furnaces for residential space and DHW heating.

Kohler et al. [62] developed a mass, energy, and monetary flow model of the German building sector. They recognized the building stock as the largest economic, physical, and cultural capital of industrialized countries, although the stock is not yet well quantified. To overcome this lack of data, they decomposed survey data into basic elements and classed them. While they state they are "reference" buildings and not "typical", they are associated with "age-use" classifications characteristic of archetypes. Each group was broken down into detailed elements such as window type. Using these elements they developed building specifications which comprise the materials and operations with respect to the building. Included in their model was retirement and replacement of both buildings and appliances. The authors found their bottom-up model was in agreement with other studies and energy surveys.

Huang and Broderick [63] developed an EM model of space heating and cooling loads of the American building stock using 16 multifamily and 45 single-family "prototypical" residential buildings. These archetypes were simulated in 16 different regions; some archetypes were simulated in as many as six regions. The authors utilized DOE-2.1, a building energy simulation program supported by the USA Department of Energy [64]. Building heating and cooling loads were disaggregated to show the contributions from the walls, roof, windows, infiltration, and internal gains by setting the thermal conductivity of each component to zero. They also included plant efficiencies, accounting for part-load efficiency and air-conditioner efficiency; however, only furnace/air-conditioner plants were modeled owing to the source of the archetypes from the Gas Research Institute. The authors utilized building population estimates provided by [8] to scale their results up to a national value. This was accomplished by normalizing the archetypes' energy consumption by heated floor area and multiplying by the national floor area value.

Jones et al. [65] developed an energy and environmental prediction model which utilized GIS techniques. They used a unique technique that augments archetypes with additional information based on a "drive-pass" survey. The model employs the UK Standard Assessment Procedure to simulate a dwelling based on building fabric, glazing, ventilation, water heating, space heating, and fuel costs. To reduce information collection time and effort, residences with similar characteristics were grouped and modeled by an archetype. The augmentation process was accomplished by using GIS to estimate building area, historical sources to estimate age, and the drive-pass (the process of assessing building characteristics from the sidewalk) to determine storeys, chimneys, and the ratio of window to wall area.

Using the developed archetypes (five age groups and twenty built forms) augmented with individual characteristics, the authors simulated the energy consumption of each dwelling in Neath Port Talbot, UK. Using GIS they illustrate the high consumption areas and those dwellings which have high potential for upgrades, as shown in Fig. 6.

Shipley et al. [66] developed archetypes of different Canadian government building types to represent over 3500 buildings. The archetypes were based on categories such as type, floor area, and age. They developed the commercial energy and emissions analysis model which utilizes ASHRAE's modified bin method, which is described by [67]. Archetypes reduced their simulation efforts as the average building accounted for the large group of diverse buildings. They calibrated the model using supplied energy consumption information from a subset of the buildings and used the model to determine the impacts of building envelope improvements.

Carlo et al. [68] took a different approach to the development of archetypes to represent Brazilian commercial buildings. Using previous simulation results of 512 buildings, the authors determined the primary variables of a building energy regression equation to be roof area ratio, façade area ratio, and internal load density. Combinations of these variables were used to develop 12 archetypes which were augmented with additional variables for parametric simulation. This resulted in 695 prototype buildings which were simulated in DOE-2.1 to determine their energy consumption. The results were used in the assessment of potential building code changes.

Shimoda et al. [69] developed a residential end-use energy consumption model on the city scale for Osaka, Japan. They developed 20 dwelling types and 23 household (occupant) types to represent the variety of houses within the city. Each dwelling type (not detailed in the paper) was modeled using conductive heat transfer analysis; however, each dwelling was considered to have identical insulation levels based on 1997 commercial offerings. This identical insulation level is a major drawback. Households were developed based on the number of family members, appliance ownership levels, and appliance ratings. Each archetype was simulated and multiplied by the number of dwellings it represents. The authors found two interesting results from their technique: the total estimated residential energy use is less than historical values because "unreasonable" energy use (e.g. leaving lights on) was not accounted for, and estimated unit energy consumption is larger than statistical values which they attribute to surveys focusing on larger families.

Wan and Yik [70] took an alternate approach to archetypes and focused on solar gains. After conducting a survey of typical housing characteristics in Hong Kong including floor plan, they developed a single archetype of 40 m^2 floor area with a rectangular living and dining room, two bedrooms, kitchen, and a bathroom. They applied typical characteristics including wall thickness, window to wall ratio, glass thickness and wall absorptivity. To introduce variety, they rearranged the floor plan layout and orientation while maintaining the size and room geometries; this resulted in different window areas facing the sun. In addition they specified different family types and use profiles. They utilized HTB2 (heat-transfer) and BECRES (air-conditioning) simulation engines described by [71,72]. They found their estimates of air conditioner energy consumption to be large when compared to historical statistics and they decreased this difference by reducing appliance usage and ownership level within the dwellings. After the modification the predicted energy consumption compared well with statistics.

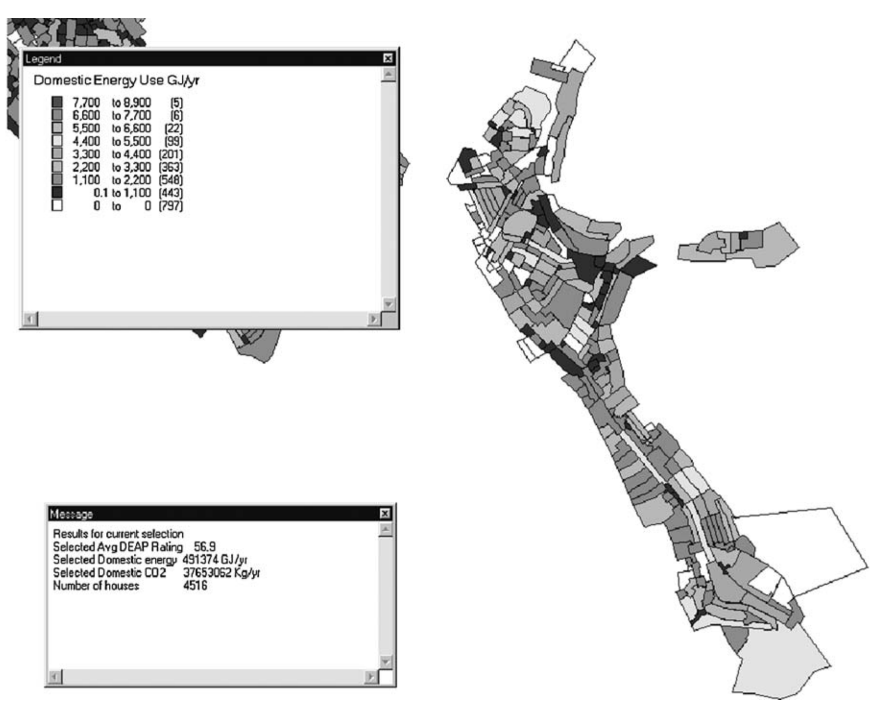

Fig. 6. Domestic energy intensity of individual residences in Neath Port Talbot [65].

Yao and Steemers [73] developed a model based on four typical UK housing topologies: flat, semi-detached, detached, and mid-terraced. Using national appliance ownership distributions, average appliance use, and average appliance rating, the authors generated random daily aggregate appliance energy consumption profiles. They used the thermal resistance method developed by the Martin Centre to calculate heating losses. They generated a regional profile based on 100 generated households and found it to be in agreement with national statistical data.

Palmer et al. [74] developed a model of the UK housing stock using 431 archetypes. They used the BREDEM-8 Building Research Establishment tool which is a monthly heat flux simulation program to model the required SH and DHW heating energy consumption [75]. Occupant and appliance heat gains are calculated based on distributions and DHW consumption is based on typical values. Their model encompasses trends of construction/demolition and demographic changes to estimate the energy consumption of the residential sector through 2050.

Petersdorff et al. [76] modeled the EU-15 building stock by examining five standard buildings with eight insulation standards. They used Ecofys's built environment analysis model (BEAM) to calculate the heating demand for three climatic regions. The three house types included in the model were terrace, small apartment, and large apartment. The eight insulation standards applied to the buildings were determined based on typical values for the climatic conditions and building vintage found in EU countries. The authors modeled different scenarios of retrofit and construction/demolition, and attempted to extend the model to smaller housing types. They found their models corresponded well with statistical data.

To extend the archetype methodology beyond its typical position of limited variety, Nishio and Asano [77] developed an archetype generation tool based on the Monte-Carlo technique. The authors utilized numerous statistics, surveys, and conventional datasets from Japan to define both the distribution and range of housing variables. Their house generator uses the Monte-Carlo technique to define attributes for each archetype based on probability assumptions. It then develops hourly patterns of energy consumption for common activities, and aggregates and applies these on a monthly basis as a function of the proposed family composition. While the number of generated houses is variable, the generator relies on 34 different family types and 47 different climatic regions. In an example, they generate and analyze 10,000 houses.

Clarke et al. [78] focused on the main determinants of energy demand within the Scottish building stock to create representative thermodynamic classes. Using the following determinants and their value or level, they developed 3240 classes: insulation level (6), capacity level (2), capacity position (3), air permeability (3), window size (3), exposure (5), and wall to floor area ratio (2). Each class was modeled using the building performance simulation software ESP-r to determine the thermal energy requirements of the dwelling [79]. System information such as heating/cooling, ventilation, DHW, and lighting was then applied to calculate the total energy consumption of the dwelling. The results were incorporated into a tool for comparative analysis and assessment of the impact of improvement measures upon the stock.

5.2.3. Samples

While archetypes provide a limited representation of the regional or national housing stock due to the limited variety of archetypes that can reasonably be defined, the use of actual house samples with the EM can realistically reflect the high degree of variety found in the actual housing stock, provided that the sample size is sufficiently large. As this form of EM modeling is data intensive, its application has been limited.

Farahbakhsh et al. [80] developed a model of the Canadian housing stock based on 16 archetypes augmented with data from 8767 actual houses. As the house data came from a national housing survey database that is statistically representative of the Canadian housing stock, weights of house representation were provided for the purpose of scaling the consumption up to provincial and national values. An individual house input file was generated for each of the 8767 houses and simulated using Natural Resources Canada's HOT2000 monthly bin type building simulation software [81]. As energy billing data was available for 2524 houses, these were used in the calibration procedure to correct data conversion errors in the input files. The national consumption estimate was found to be in agreement with other studies. Using this national residential energy model, Guler et al. [82,83] studied the impact and economic analysis of energy efficiency upgrades on energy consumption and greenhouse gas emissions. They found energy savings and greenhouse gas reduction potential for upgrades of heating systems to be 8%, basement insulation to be 4%, and programmable thermostats to be 2% (approximate values reported here). Using the energy costs at that time, the major upgrades were not found to be economically feasible. Aydinalp et al. [84] updated the model of [80] by using housing data from 1997 and found that the UEC had increased by 1.8%.

Larsen and Nesbakken [85] developed a model of Norway's housing stock using household information from 2013 dwellings. They describe the simulation engine, ERÅD, and identify its fundamental weakness as the high number of numerical inputs. Significant efforts were required to calibrate the model which is not desirable as the engineering technique should calculate appropriate initial values. They note that while it is possible to account for every end-use in an engineering model, unspecified end-uses must be estimated. Instead, this was accounted for by calibrating the known end-uses, resulting in a slight overestimate of each end-use contribution. The authors found SH and DHW to be approximately 42% and 24% of total consumption, respectively.

Two other sample EM models deal with commercial buildings. Ramirez et al. [86] modeled 2800 commercial premises of California using a modified version of eQuest building simulation software [87]. Combining survey information from all 2800 buildings, their energy billing data, sub-metered data from 500 buildings, and current year weather data from 20 stations, the authors modified predefined footprint templates to represent each building. The model numerically and visually displayed the hourly results of each building simulation. Calibration was conducted on each building model by a simulation specialist and consisted mainly of verifying significant end-uses and their ranges. Final alterations were made by adjusting schedules and operating hours. During the calibration process it was found that occupation, or lack thereof, of the building has unexpected impacts. Specifically, the assumption that AL is turned off at the end of the business day was found to be false.

Griffith and Crawley [88] developed a similar model. They modeled 5430 buildings that comprise the Commercial Buildings Energy Consumption Survey Database (CBECS) and included weighting factors for extrapolation to national results for the USA. However, their focus was the "technical potential" of the sector (i.e. the lowest feasible energy consumption) and thus the 2005 building code requirements were applied to each building. Additional information not included in the CBECS was developed using ASHRAE standards and pseudo-random application of average parameter distributions, such as infiltration. They developed a rule based pre-processor to translate the parameters into "shoebox" building input files for simulation by the USA Department of Energy's EnergyPlus software [89]. Simulations were conducted on a computer cluster. They determined that the high number of building records was a disadvantage as it required significant computing capability. They recommend this technique only when results must reflect national implications on a limited number of scenarios. They recommend a smaller database size for high numbers of parametric simulations.

Swan et al. [90] is developing a national residential energy model of Canada using a detailed database of nearly 17,000 houses. The housing database, described by [12], is a selected subset from a national home energy audit program database that characterised the thermal envelope of each dwelling, including an air tightness test. The database of houses descriptions is presently being converted to detailed house models for building energy simulation using the software ESP-r [79]. The detailed house descriptions and high-resolution simulation (one hour time-step) allow for an assessment of the impact on energy consumption due to the application of new technologies to appropriate houses.

6. Critical analysis of top-down and bottom-up approaches

The top-down and bottom-up approaches each have distinct similarities and differences, as well as advantages and disadvantages. Two of the most critical issues that characterize these approaches are the required input information and the desired range of modeled scenarios.

6.1. Strengths and weaknesses of the top-down approach

Top-down approaches are relatively easy to develop based on the limited information provided by macroeconomic indicators such as price and income, technology development pace, and climate. Top-down models heavily weigh the historical energy consumption which is indicative of the expected pace of change with regards to energy consumption. This weighting may be seen in Eq. (4). Models that evaluate from a regional or national scope are useful for estimating the required energy supply and the implications of a changing economy. They falter when discontinuity is encountered. Examples of such situations include technological breakthroughs or severe supply shocks, the latter being most pronounced due to the slow turnover rate of the housing stock. Contrary to other studies and with respect to a practical sense given today's energy environment, Haas and Schipper [18] clearly identified non-elastic response due to "irreversible improvements in technical efficiency". This exemplifies the importance of including a representative technological component in top-down models. Jaccard and Bailie [57] discussed the notable dichotomy that top-down models estimate high abatement costs for reducing carbon dioxide emissions whereas bottom-up models' estimates are notably lower. They attribute this to economists' over-reliance on the autonomous energy efficiency index (AEEI) and the elasticity of substitution (ESUB). The NEMS has included both a *technology* and *distributed-generation* component [24]. This indicates that top-down modeling systems are now attempting to account for the uptake of new technologies. While these techniques may account for future technology penetration based on historic rates of change, they do not provide an indication of the *potential* impacts of such technologies and are therefore not helpful in the development of policy or incentive to encourage them.

6.2. Strengths and weaknesses of the bottom-up approach

Bottom-up statistical techniques bridge the gap between detailed bottom-up end-use energy consumption models and regional or national econometric indicators. These techniques are capable of encompassing the affects of regional or national economic changes while indicating the energy intensity of particular end-uses. The primary information source of the bottom-up SM is energy supplier billing data. While this is private information, the sheer quantity and quality of this information warrants further compilation and use. By disaggregating measured energy consumption among end-uses, occupant behaviour can be accounted for. This is a distinct advantage of the SM over the EM. Of the three bottom-up SM techniques, common regression is the least favoured as the utilized inputs vary widely among models, limiting their comparison. In contrast, CDA is focused on simplifications of end-uses and is therefore easily ported to other locations and its predictions are comparable among different studies. As appliances currently on the market vary widely in size and less in technology, the addition of such information could be beneficial for future CDA studies. Although the NN technique allows for the most variation and integration between end-uses, resulting in the highest prediction capabilities (Aydinalp et al. [91]), its coefficients have no physical significance. This is a severe drawback. Estimation of individual end-uses was demonstrated by removing their presence in the NN model. However, due to the interconnectivity between each end-use, the removal of many end-uses, individually or simultaneously, reduces the level of confidence in the resulting predictions. Furthermore, bias of the energy estimation error was found when using the NN technique. Aydinalp-Koksal and Ugursal [47] provide a detailed review and comparison of specific CDA, NN, and EM models.

Bottom-up EM techniques rely on more detailed housing information. These models explicitly calculate or simulate the energy consumption and do not rely on historical values, although historical data can be used for calibration. Larsen and Nesbakken [85] developed both engineering (samples) and statistical (CDA) models to compare their results. They noted that the engineering technique requires many more inputs and has difficulty estimating the unspecified loads, but while the statistical technique reduces both of these issues it is hampered by multicollinearity resulting in poor prediction of certain end-uses.

If the objective is to evaluate the impact of new technologies, the only option is to use bottom-up EM techniques. This is a point of emphasis because compared to taxation and pricing policies, technological solutions are more likely to gain public acceptance to reduce energy consumption and the associated greenhouse gas emissions. The EM is capable of modeling on-site energy collection or generation such as active or passive solar and co-generation technologies.

The most apparent drawback of the EM is the assumption of occupant behaviour. Because the effect of occupant behaviour can significantly impact energy consumption, the assumption of occupants' activities is not trivial. Statistical techniques based on monthly data are capable of incorporating the effects of occupant behaviour, although they may be inappropriately applied to end-uses. Also, the high level of expertise required in the development and use of the EM may be considered a drawback. The computational limitations discussed by Griffith and Crawley [88] regarding large numbers of simulations are no longer critical as the data processing capability of computers is continuing to increase rapidly.

To address the shortcomings of both the EM and the statistical based models, research is currently being conducted by Swan et al. [90] to develop a "hybrid" EM and NN model for the Canadian housing sector that will incorporate a NN model to predict the highly occupant sensitive DHW and AL energy consumption, while using the EM to predict the SH and SC energy consumption.

6.3. Attributes and applicability of the modeling approaches

The important attributes of the three major residential energy modeling approaches, namely the top-down, bottom-up statistical and bottom-up engineering, are shown in Table 3. Each approach

Table 3
Positive and negative attributes of the three major residential energy modeling approaches.

	Top-down	Bottom-up statistical	Bottom-up engineering
Positive attributes	• Long term forecasting in the absence of any discontinuity	• Encompasses occupant behaviour	• Model new technologies
	• Inclusion of macroeconomic and socioeconomic effects	• Determination of typical end-use energy contribution	• “Ground-up” energy estimation
	• Simple input information	• Inclusion of macroeconomic and socioeconomic effects	• Determination of each end-use energy consumption by type, rating, etc.
	• Encompasses trends	• Uses billing data and simple survey information	• Determination of end-use qualities based on simulation
Negative attributes	• Reliance on historical consumption information	• Multicollinearity	• Assumption of occupant behaviour and unspecified end-uses
	• No explicit representation of end-uses	• Reliance on historical consumption information	• Detailed input information
	• Coarse analysis	• Large survey sample to exploit variety	• Computationally intensive
			• No economic factors

meets a specific need for energy modeling which corresponds to its strongest attribute:

- Top-down approaches are used for supply analysis based on long-term projections of energy demand by accounting for historic response.
- Bottom-up statistical techniques are used to determine the energy demand contribution of end-uses inclusive of behavioural aspects based on data obtained from energy bills and simple surveys.
- Bottom-up engineering techniques are used to explicitly calculate energy consumption of end-uses based on detailed descriptions of a representative set of houses, and these techniques have the capability of determining the impact of new technologies.

Given today’s energy considerations that encompass supply, efficient use, and effects of energy consumption leading to the promotion of conservation, efficiency, and technology implementation, all three modeling approaches are useful. Top-down models are the clear winner in supply considerations as they are heavily weighted by historical energy consumption which places their estimates of supply within reason. Bottom-up statistical models can account for occupant behaviour and use of major appliances, which leads to the identification of behaviours and end-uses which cause consumption of unwarranted quantities of energy. Lastly, bottom-up engineering models may identify the impact of new technologies based on their characteristics and account for the wide degree of variety within the housing stock.

As the effects and limitations of conventional energy sources (i.e. fossil fuels) are widely acknowledged, alternative energy sources and technologies are continuously being investigated and developed. To determine the impacts of such new developments requires a bottom-up model. This is further exemplified by the focus being placed on efficiency and on-site energy collection and generation at individual houses. During this period of rapid technological development and implementation, the bottom-up techniques will likely provide much utility as policy and strategy development tools.

First version received June 2002; *final version accepted October* 2004 (*Eds.*)

Recent efforts to restructure electricity markets have renewed interest in assessing how consumers respond to price changes. This paper develops a model for evaluating the effects of alternative tariff designs on electricity use. The model concurrently addresses several interrelated difficulties posed by nonlinear pricing, heterogeneity in consumer price sensitivity, and consumption aggregation over appliances and time. We estimate the model using extensive data for a representative sample of 1300 California households. The results imply a strikingly skewed distribution of household electricity price elasticities in the population, with a small fraction of households accounting for most aggregate demand response. We then estimate the aggregate and distributional consequences of recent tariff structure changes in California, the consumption effects of which have been the subject of considerable debate.

1. INTRODUCTION

Recent efforts to restructure electricity markets have renewed interest in electricity demand and pricing. This interest reflects a broad desire to improve the efficiency of electricity markets, and policy-makers' concerns over the impact of price changes on consumers. How new pricing mechanisms would affect households' consumption and expenditures is a matter of considerable uncertainty, however. This uncertainty has provoked controversy and debate in the regulatory policy arena, hampering market reforms.

Using econometric methods to assess the effects of electricity price changes presents several challenges. These include the nonlinear structure of tariff schedules, aggregation of metered consumption behaviour over time and appliances, and the interdependence of energy use with longer-term household decisions over appliance ownership and dwelling characteristics. The first two issues introduce complex simultaneity problems between marginal prices and consumption. The third issue imposes high data requirements (information on household-specific appliance holdings and residence features), and creates heterogeneity in consumption responses related to the characteristics of these durable goods. When the researcher's objective is to develop a model for simulating the effects of prospective tariff changes, ignoring these issues will provide an incomplete assessment of demand responses and potentially misleading predictions of a new tariff's consumption and revenue consequences.

In this paper, we estimate a model of household electricity demand that can be used to evaluate alternative tariff designs. The model focuses on the heterogeneity in households' demand elasticities, their relation to appliance holdings and other household characteristics, and how they inform household consumption responses to complex (nonlinear) price schedule changes. Although these issues have received attention in the literature, few (if any) studies have addressed them in an integrated way.[1] This shortcoming is notable in that theory suggests that the effects of an alternative tariff design on a diverse population will depend on the heterogeneity in consumers' price elasticities as well as their consumption levels. We address these features using a model of endogenous sorting along a nonlinear price schedule, and a group-wise specification of price-sensitivity heterogeneity based on household appliance ownership. This model reveals a rich, highly asymmetric shape to the population distribution of households' price elasticities. It also indicates a larger aggregate price elasticity of residential electricity demand than prior studies that ignore these issues.

We estimate the model using data for a representative probability sample of California households from the *Residential Energy Consumption Survey* of the U.S. Department of Energy. The rich detail on appliance holdings and dwelling characteristics in these data allow us to model the considerable variation in households' electricity use and sensitivity. We have supplemented the *Survey* by matching each sample household with its complete, seasonally varying electric rate schedule. The use of precise rate schedule information is a central feature of the analysis, both to minimize specification error in estimation and to evaluate individual behavioural responses to alternative rate structures. To lend credence to the specifications and results, we conduct out-of-sample tests of the model that show how well it predicts consumption responses to new price changes.

We then use the model to study the effects of a controversial new tariff design in California. Following an electricity supply crisis in 2000–2001, regulatory authorities approved a novel, five-part tariff structure for residential electricity consumption. This design was intended to induce energy conservation, raise additional revenue for utilities, and minimize expenditure changes for lower-income households. Due to its unprecedented form, however, little was known about how well the new system would achieve these objectives prior to its adoption. We show how such uncertainties can be evaluated prospectively using the sample data, and contrast our estimates with methods employed by public agencies in California and elsewhere.

The next section lays the econometric groundwork for our empirical methods, and highlights how our approach differs from prior studies. Our treatment of the endogenous sorting problem that occurs with nonlinear prices builds upon Hanemann's (1984) and Hausman's (1985) choice models given nonlinear budget constraints. Our approach also handles two important aggregation-related problems common to electricity demand research. Section 3 then develops the empirical specification. Following prior work, this model explains heterogeneity in households' electricity price elasticities in terms of appliance holdings and use. Section 4 discusses estimation via an exact nonlinear method of moments, and Section 5 summarizes the data. Sections 6 and 7 present estimation results and elasticities, including out-of-sample validation tests of the model. In Section 8 we then illustrate how the model and methods lend themselves to analysing prospective tariff design changes, such as California's complex new tariff structures.

2. MODELLING DEMAND WITH NONLINEAR PRICES

Although economic theory offers considerable guidance on how consumers will respond to nonlinear prices, econometric treatments of estimation and identification in this setting remain

1. Taylor (1975) contains an early treatment of nonlinear tariffs in empirical work. More sophisticated methods followed Burtless and Hausman's (1978) work on closely related issues in the analysis of labour supply under nonlinear income taxation. Surprisingly little of these econometric techniques have permeated the (considerable) literature on electricity demand; notable exceptions are Maddock, Castano and Vella (1992) and Herriges and King (1994). A greater consensus has emerged on the importance of incorporating household-level appliance stock information into electricity demand analyses, as well as empirical methods for doing so; see Parti and Parti (1980), Dubin and McFadden (1984), Dubin (1985), and EPRI (1989).

incomplete. This section summarizes the problems inherent in prior estimation strategies, motivates and describes our econometric approach, and connects it to related econometric literatures.

2.1. *Specification and identification*

Most nonlinear price schedules take the form of multi-part tariffs. Since Gabor (1955), economists have realized that multi-part tariffs imply that the consumer faces a nonlinear (*i.e.* a kinked) budget constraint. The demand behaviour of a utility-maximizing consumer thus depends not on the average price, nor any single marginal price, but on the entire price schedule. The standard econometric approach to demand analysis in this setting, which traces to Hall (1973), is to "linearize" the budget constraint. This amounts to using the plane tangent to the consumer's nonlinear budget constraint at the optimal consumption bundle as its linear approximation. By doing so, one can express demand under nonlinear pricing in terms of the ordinary demand function of classical consumer theory, which assumes a linear budget constraint.

To be specific, let $x(p, y)$ be the ordinary demand function that indicates the consumer's desired quantity facing a constant (marginal and average) price p and income y. Suppose, however, that the consumer faces an increasing price schedule $s(p)$ of the form depicted in Figure 1. Here the consumer pays a low price p_1 for each unit up to the quantity $\bar{x}$, and a higher price p_2 thereafter. Then the optimal consumption level x^* satisfies

$$x^* = x(p^*, y^*) \tag{1}$$

where p^* is the slope of the approximating linear budget constraint and $y^* = y + \bar{x} \cdot (p^* - p_1)$. In economic terms, p^* is the consumer's equilibrium marginal willingness-to-pay and y^* is the income level that would induce consumption x^* at this (constant) price. With (1), the demand specification problem under nonlinear pricing can be recast in terms of the ordinary demand function familiar to applied work. Note that both p^* and x^* are endogenously determined, according to the three-equation system consisting of (1), the expression for y^*, and the nonlinear price schedule $s(p^*)$.[2]

Nearly all previous studies of household electricity demand have based estimation—either implicitly or explicitly—on a single-equation analogue of equation (1). Because the marginal price is simultaneously determined by a supply equation and a demand equation, standard econometric arguments imply that ordinary least squares estimation using p^* will yield biased and inconsistent estimates of demand parameters. Recognizing as much, most previous studies have used either an exogenous proxy for the marginal price or instrumental variables (IV) procedures in estimation. While either method can alleviate the endogeneity problem, both introduce biases of their own: the former due to mis-specification of the appropriate marginal price, and the latter because of the difficulty in finding good instruments (that do not *a priori* belong in the demand equation) in this setting.

To elaborate on the latter point, the natural set of instruments in this context are the components of the price schedule itself. This idea appears in early work by McFadden, Puig and Kirshner (1977) and others. An important shortcoming of this approach, however, is that there may be little or no price schedule variation in the data. This is a common situation in nonlinear pricing applications, as the data are often provided by a single firm that charges either one tariff,

2. The analysis with a decreasing price schedule is slightly more complex, because of the possibility that demand may have multiple crossings of the price (supply) schedule. In that event, these three equations have multiple solutions and a fourth equation (involving the indirect utility function) is needed to determine consumption. This analysis is feasible if the econometric demand specification admits a known indirect utility function; see, *e.g.* Hausman (1985).

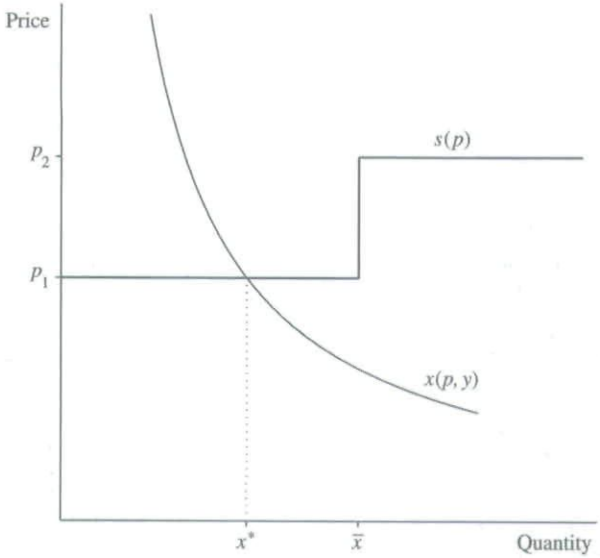

FIGURE 1
An increasing two-tier price schedule

or a few very similar ones, to all consumers. Researchers thus face a canonical weak instruments problem that can result in imprecise and misleading price-elasticity estimates.[3]

A second, and more general, concern arises when consumption decisions are aggregated over time or over distinct services. In the presence of nonlinear pricing, such aggregation often makes IV procedures infeasible.[4] For example, when the consumption data are aggregated over billing periods, the consumer's actual marginal prices are typically not observed. Thus there is no way to construct a proper IV estimator: the endogenous (sequence of) marginal prices are not available to project onto any instrument. Similar difficulties arise if consumption outcomes are aggregated over nonlinearly priced goods or services, rather than over time.[5]

Data aggregation problems of this sort are nearly universal in electricity demand studies. They occur both because a household's electricity meter aggregates consumption of numerous distinct appliance "services" (addressed further in Section 3), and because publicly available data often record consumption over annual (or other) intervals covering multiple billing periods. The predominant treatment of this latter issue in the literature has simply been to ignore it, proceeding as if the household faced a constant (marginal) price over the course of the year. This not only mis-specifies the prices consumers face, it assumes away the economic effects of interest.

In this paper we handle these difficulties in an integrated way. The starting point is the true reduced form of the "supply equals demand" equilibrium condition in (1); that is, solving the three-equation system above for x^* as a function of the price schedule. We do so here assuming the consumer's ordinary demand function (demand at a constant price p) takes the

3. Dubin (1985) shows that ignoring simultaneity problems can produce substantially biased electricity demand elasticities. Maddock *et al.* (1992) show that one common IV approach fails to correct well for the simultaneity bias, resulting in estimated price elasticities that are biased toward the slope of the supply curve.

4. We thank an anonymous referee for emphasizing this point.

5. This problem also arises in other econometric applications. An example is the analysis of aggregated retail scanner data for consumption goods, which are often sold using nonlinear forms of pricing (volume discounts, limited-quantity coupons, 2-for-1 offers, etc.). Policy-makers that use such data are now evidently aware of these aggregation biases; see FTC (2002).

econometric form

$$x(p, y, z, \varepsilon; \beta) \tag{2}$$

where z represents observed consumer characteristics, ε unobserved consumer characteristics, and β a set of parameters to be estimated. To avoid unnecessary technicalities, assume demand is strictly increasing in ε and strictly decreasing in p.

Facing an increasing two-tier price schedule, the reduced form for the household's consumption level x^* as a function of the price schedule is

$$x^* = \begin{cases} x(p_1, y, z, \varepsilon; \beta) & \text{if } \varepsilon < c_1 \\ \bar{x} & \text{if } c_1 < \varepsilon < c_2 \\ x(p_2, y_2, z, \varepsilon; \beta) & \text{if } \varepsilon > c_2 \end{cases} \tag{3}$$

where $y_2 = y + \bar{x} \cdot (p_2 - p_1)$ and c_j is the solution to $x(p_j, y_j, z, c_j; \beta) = \bar{x}$ with $y_1 = y$ (that is, c_j is the maximum (for $j = 1$) or minimum (for $j = 2$) value of ε for which consumption occurs on tier j). Equation (3) states that consumption is given by demand at the low price if the first tier is on the margin, by demand at the high price plus an income effect if the second tier is on the margin, and by the quantity $\bar{x}$ when demand crosses supply in the "gap" between the two tiers of the price schedule.[6] The lower and upper cut-off values c_1 and c_2 satisfy $c_1 < c_2$ for any downward-sloping demand function, provided that income effects are not too large.[7]

It is useful to be clear about why estimating the single reduced-form equation (3) can separately identify the effect of price on demand and supply (*e.g.* β in (2)). Intuition from classical supply-and-demand simultaneity in linear econometric models suggests that additional exclusion restrictions are necessary—tantamount to assuming that viable instruments are available. With nonlinear pricing problems, however, this is not the case. Demand is identifiable here because (i) the supply schedule has constant-price segments, and (ii) the conditional distribution of ε (given the marginal price) is computable. Intuitively, one can use the variation in consumption among all households on the *same* tariff segment to identify the non-price components of demand.[8] Given that, the effect of price can be determined from the remaining difference in average consumption between households on *different* tariff segments, less the average difference in their unobserved characteristics. The latter is computable from the marginal distribution of ε and the price schedule. Researchers can therefore estimate demand without price schedule variation, provided one is willing to place some distributional restrictions on ε. Of course, when there is price schedule variation in the data, this will provide a second "source of identification" for the demand specification (2).

In sum, by solving-out the marginal price to obtain (3), the simultaneity problems arising in econometric analyses using (1) can be avoided. In addition, if one proceeds from an empirical specification of the ordinary demand function that is consistent with (or perhaps derived from) a utility specification, then (3) indicates precisely how the individual terms of a nonlinear price

6. The term $\bar{x} \cdot (p_2 - p_1)$ that is added to income in the third case in (3) is the infra-marginal price discount: the difference between the expenditure necessary to purchase the higher quantities $x^* > \bar{x}$ under nonlinear pricing, and that necessary to purchase x^* at a constant price of p_2.

7. Technically, the case conditions in (3) are correct only if certain restrictions on preferences hold. For a normal good (one whose consumption rises with income), these amount to assuming that the income effect is not "too large"; or, more specifically, that the income effect of the infra-marginal discount does not dominate the substitution effect of the higher marginal price. If this fails, the conditioning-event inequalities on the R.H.S. of (3) are more complex.

8. This argument ignores income effects (cf. note 7) and confounding due to aggregation over time (more about which further below).

schedule enter the demand decision. This provides a framework for predicting how consumption would change under an entirely different price schedule.

2.2. *Estimation issues*

From an econometric perspective, equation (3) is a nonlinear censored regression model in which the censoring occurs in the interior of the distribution of outcomes rather than the tails. Such models are generally estimated by maximum likelihood methods, using the discrete structure in (3) to derive the change-of-variables from an (assumed) marginal distribution of ε to the distribution of x^*. Burtless and Hausman (1978), with later extensions by Hausman (1985), Moffitt (1986), and others, develop likelihood functions for models with this structure. Unfortunately, maximum likelihood estimation quickly becomes computationally intractable when the consumption outcomes from a mixed discrete/continuous model are aggregated over time. This problem renders likelihood methods infeasible for our application.[9] Consequently, we pursue a moment-based approach to estimation.

Conditional on the observables, (3) can be integrated piecewise to obtain

$$E(x^* \mid \cdot) = E_\varepsilon[x(p_2, y_2, z, \varepsilon; \beta)] + h(p_1, p_2, \bar{x}, y, z; \beta) \tag{4}$$

where $h(\cdot) \equiv \tau_2 - \tau_1$ is a sorting correction function defined by the truncated moments

$$\tau_j = \int_{-\infty}^{c_j(\beta)} [\bar{x} - x(p_j, y_j, z, \varepsilon; \beta)]\, dF_\varepsilon, \qquad j = 1, 2, \tag{5}$$

with c_1, c_2 defined in (3) and $y_1 = y$. These expressions do not place restrictions on $x(\cdot)$ or how ε enters it (beyond integrability of demand and monotonicity in ε). Although complex in the general form, the moments in (5) that correct for the nonlinearity of the price schedule are straightforward to evaluate for most error specifications in applied work. For example, if F_ε is $N(0, \sigma^2)$ and ε enters demand (2) additively, then expected consumption simplifies to

$$\begin{aligned} E(x^* \mid \cdot) = {} & [x(p_1, y, z; \beta) - \sigma\lambda_1]\Phi_1 + \bar{x} \cdot (\Phi_2 - \Phi_1) \\ & + [x(p_2, y_2, z; \beta) + \sigma\lambda_2]\,(1 - \Phi_2) \end{aligned} \tag{6}$$

where Φ_j is the standard normal distribution evaluated at $c_j(\beta)/\sigma$, ϕ_j the normal density at $c_j(\beta)/\sigma$, $\lambda_1 = \phi_1/\Phi_1$, and $\lambda_2 = \phi_2/(1 - \Phi_2)$.

Equation (6) highlights a useful parallel to more familiar econometric selection models. The terms in square brackets in (6) correct for the fact that, given the observables, consumers that sort onto the lower marginal price are different in their unobservable characteristics from those who choose the higher-tier price. This parallels conventional sample-selectivity problems inasmuch as the econometric complications in both settings stem from endogenous sorting along a budget constraint. Unlike traditional models of labour supply (such as Heckman, 1974), however, here the sorting occurs between segments of a nonlinear budget constraint. This situation generates greater information about the distribution of consumer preferences than sorting between interior and boundary solutions along a linear constraint, which makes (4) more complex than standard selection–correction models.[10]

9. To illustrate, the likelihood function for a single (monthly) consumption outcome x^* of the model (3) is a mixed continuous/discrete function with three discrete segments (one for each case in (3)). The likelihood function for the sum of 12 months' consumption outcomes therefore involves 3^{12}, or 531,441 distinct segments. While there is some redundancy involved, the task of evaluating such a likelihood function (for use in either direct or simulated likelihood methods) appears quite burdensome.

10. At the risk of confusing matters, there is one other difference between the present analysis and traditional models of labour market supply. The analysis here is more complicated because the supply and demand system is non-

The moment expressions in equations (4) and (5), and its interpretation as a selection problem, suggest that it might be possible to take a semi-parametric approach to estimating this model (following Ichimura (1993) or Das, Newey and Vella (2003)). Such methods are not designed to handle situations, such as ours, where there is no ancillary selection information about which segment of the budget constraint is marginal. That is, there are no covariates that predict a household's tariff tier that can be *a priori* excluded from the demand specification. One paper that appears to have made progress in this area is Blomquist and Newey (2002), in the context of modelling labour supply decisions subject to nonlinear income taxation. Their non-parametric approach does not appear adaptable to the present setting, unfortunately, for two reasons. First, identification appears to require considerable cross-sectional variation in price schedules across sample observations. While not a problem for the labour supply context (due to wide wage dispersion), this is a significant limitation in nonlinear pricing applications. The second, and more subtle, issue is that the non-parametric literature cannot yet handle cases where the observed outcome is the aggregation of several distinct consumption decisions that are interdependent. Demand is then implicitly defined by an equilibrium relation for which the marginal effects (of price schedule changes) may not be non-parametrically identified. Such a structure is inherent in electricity demand analyses, due to the aggregation of consumption across appliances.[11]

These considerations necessitate a parametric approach to modelling F_ε in nonlinear pricing problems, at least in our context. In estimation we use (6), which fits our data well. In general, restrictions on F_ε sufficient to evaluate the truncated moments in (5) are necessary to estimate demand elasticities and other quantities dependent on (2), in the absence of considerable (and exogenous) variation in price schedules. This, of course, raises the issue of whether such restrictions are valid for the particular application at hand. We take a formal approach to validating our model using out-of-sample testing in Section 7.

2.3. *Aggregation over time*

A method of moments framework also allows us to handle complications posed by data aggregation over time. In practice, electricity tariffs apply to households' consumption on a monthly basis. In contrast, the data available to us provide only *annual* household electricity consumption. This temporal mismatch is a potential source of bias, as the effects of prices and other time-varying covariates will tend to be confounded in the data. For example, a decrease in a household's cumulative demand over a period of several cooler-than-usual summer months could be due solely to the effect of weather, or due to an increase in seasonal electricity tariffs during the summer, or due to a composition of these two simultaneous effects. With only annual data, it is difficult to disentangle and separately identify the direct effect of marginal price changes. Yet estimating this effect is precisely what is required if we are to measure the effects of changing (monthly) tariff schedules.[12]

recursive. That is, in traditional labour supply models, the individual's labour supply function depends on the market wage, but the market wage is constant irrespective of the labour hours supplied. The slope of the budget constraint is therefore exogenous. In the present analysis, the quantity demanded depends on the marginal price (through substitution behaviour) and the marginal price depends on the quantity consumed (through the price schedule). This feature eliminates triangular-system approaches to estimation (*e.g.* Newey, Powell and Vella, 1999).

11. To elaborate, aggregation across appliances implies that a household's electricity demand x^* takes the implicit form $x^* = \sum_k f_k(p(x^*), z)$, where $p(x^*) \in \{p_1, p_2\}$ is the marginal price (which depends on total consumption) and f_k is the demand for the k-th appliance's services. Projecting observed values of x^* onto $\{p_1, p_2, z\}$ non-parametrically describes the equilibrium relation between these variables, not the marginal effect of changing the price schedule on demand. The latter is the effect of empirical interest.

12. Similar temporal aggregation problems occur in other contexts, such as when workers' wages are determined weekly (including overtime), but only monthly or annual data are available.

Addressing this problem constructively requires modelling each monthly consumption outcome, in order to avoid mis-specifying the prices consumers actually face. It also requires information on how demand conditions changed during the year. To be precise, let w_t denote the observable variables affecting consumption in month t, including the applicable price schedule and that month's weather conditions. Let x_t^* denote the household's electricity consumption in month t, and $x^a = \sum_{t=1}^{12} x_t^*$ the household's annual electricity consumption. The value of x_t^* for month t is determined by (3), using the R.H.S. covariates for that month.

To estimate the model we require an expression for the expected value of annual demand, $E[x^a \mid w_1, w_2, \ldots, w_{12}]$. Exploiting linearity of expectations, we assume

$$E[x^a \mid w_1, w_2, \ldots, w_{12}] = \sum_{t=1}^{12} E[x_t^* \mid w_t], \tag{7}$$

where $E[x_t^* \mid w_t]$ is as defined in (6).[13] That is, we evaluate the (conditional) expectation of annual demand by evaluating the monthly consumption equation 12 times, using the appropriate covariates for each month. There is no simple form for otherwise calculating the expected value of annual demand.

In the empirical analysis of demand behaviour, the expected consumption equations (6) and (7) serve two roles. They can be used to estimate a model of demand that avoids aggregation biases when consumers face nonlinear tariffs of the form in Figure 1; and, given the estimated demand model, they can be used to predict how consumption would differ under an alternative tariff structure. Proceeding to the first of these objectives next, we now consider the specification of a household electricity demand function, $x(p, y, z, \varepsilon; \beta)$.

3. HOUSEHOLD ELECTRICITY DEMAND

Like many household services, electricity is not consumed directly. Rather, electricity demand is derived from the flow of services provided by a household's energy-using appliances. The durability of these appliances creates a distinction between short-run and long-run demand elasticities. The "short-run" refers to demand behaviour taking a household's existing appliance stock as given. For example, in response to an increase in the price of electricity, a household might tolerate a warmer air conditioner setting or reduce the number of hours a pool filter operates. In contrast, long-run elasticities incorporate both changes in utilization behaviour and any adjustments to the stock of appliances owned by the household.

This distinction has important consequences for modelling demand behaviour. The long-run effects of electricity price changes are an equilibrium outcome of households' appliance replacement decisions (on the demand side) and appliance manufacturers' choices of technological characteristics and prices for new appliances (on the supply side). Like most prior studies, however, our (cross-sectional survey) data do not contain the longitudinal information necessary to estimate how these replacement decisions are prompted by changing energy prices. Thus, we focus on analysing short-run demand elasticities, and leave appliance replacement decisions for subsequent research. Our results therefore describe changes in demand

13. Equation (7) makes a subtle separability assumption about the conditioning sets, which affects household substitution behaviour over time. If we assume that households consume electricity out of permanent rather than contemporaneous (*i.e.* monthly) income, the only time-varying elements in w_t are the monthly weather-related covariates and the price schedules (being seasonal). Equation (7) makes the implicit assumption that, conditional on a household's existing appliance stock, knowledge of the electricity price schedules and weather patterns for past and future months this year has no effect on the current month's consumption. While untestable directly, this is a plausible assumption since households cannot store electricity.

due to changes in appliance utilization behaviour, rather than equilibrium appliance stock adjustments.[14]

This approach to modelling electricity demand amounts to conditioning on households' existing appliance stocks. Since households vary markedly in the set of appliances they own, however, the factors influencing electricity demand in one household may differ significantly from those in the next. We address such heterogeneity by specifying electricity demand functions at the level of the individual appliance.[15] Because we do not observe the electricity consumption of individual appliances, but rather total household electricity consumption, we treat the electricity used by each of a household's individual appliances as a latent outcome. We then aggregate these appliance-level demand specifications to model household electricity demand.

Specifically, we treat total household demand as the sum of electricity used by K distinct appliance categories. These categories include space heating, water heating, air conditioning, refrigeration, pools, and the like. If a household owns an appliance of type $k = 1, 2, \ldots, K$, we assume that electricity consumption (per billing period) for the category, x_k, takes the linear form

$$x_k = \alpha_k p + \gamma_k y + z_k' \delta_k + \varepsilon_k \tag{8}$$

where p is the price of electricity, y household income, z_k a vector of observable household characteristics, and ε_k unobservable household characteristics. The unknown demand parameters α_k, γ_k, and δ_k are assumed constant across households. Depending on the appliance, the category-specific vector z_k may include household demographic information, dwelling structure characteristics, appliance attributes, and (contemporaneous billing-period) weather data. We interpret equation (8) as household demand when it faces a constant (marginal and average) price, p.

Since a household's total electricity demand is the sum of its appliances', we can aggregate (8) to obtain

$$x = \sum_k d_k \alpha_k p + \sum_k d_k \gamma_k y + \sum_k d_k z_k' \delta_k + \sum_k d_k \varepsilon_k, \tag{9}$$

where x is total household electricity consumption, $d_k = 1$ if the household owns appliance type k, and $d_k = 0$ if otherwise. This is conveniently rewritten as

$$x = \alpha p + \gamma y + z' \delta + \varepsilon \tag{10}$$

by setting $\alpha = \sum_k d_k \alpha_k$, $\gamma = \sum_k d_k \gamma_k$, and so on. Although equation (10) looks like a conventional linear demand function, the price, income, and other slope coefficients depend upon the household's appliance portfolio. Notice that we are not estimating α directly, but rather the parameters $\alpha_1, \alpha_2, \ldots, \alpha_K$ that characterize the price-sensitivity of each appliance category (and similarly for γ, δ). Thus, this specification allows households with numerous electricity-intensive appliances, such as air conditioners, swimming pools, or electric space heating systems, to exhibit different price and income elasticities than households without such appliances.[16]

14. The element of technological change in appliance manufacturers' choices makes estimating the long-run effects of electricity price changes particularly complex. One effort to do so is the EPRI Residential End-Use Energy Planning System (REEPS) micro-simulation models; see Goett and McFadden (1984). These models build on Dubin and McFadden's (1984) model of contemporaneous appliance choice and utilization decisions.

15. This latent-variables approach to modelling electricity consumption is implicit in Fisher and Kaysen's (1962) pioneering work on aggregate electricity demand. Later studies using related approaches include Parti and Parti (1980), Barnes, Gillingham and Hagemann (1981), and Dubin (1985). The present approach is sometimes termed "conditional demand analysis" in the literature (see especially EPRI, 1989 and references therein); we avoid this usage because it conflicts with similar terminology in econometric multi-level budgeting models.

16. A separate issue not examined here is that the choice of major appliances in a residence is ultimately endogenous, and may be statistically endogenous to a model of utilization behaviour. Dubin and McFadden (1984)

Equation (10) corresponds to the conventional demand function $x(p, y)$ of classical consumer theory. That is, it specifies the amount of electricity the household would consume *if* it faced income level y and a constant price p for electricity. Since the sample households face nonlinear price schedules, the optimal consumption level is given by evaluating demand using equation (3). The expected value of demand is similarly determined, by appropriately inserting the demand specification (10) into the expected consumption equation (6).

Variances. An important aspect of this model is that the household-level demand error, ε, is heteroscedastic. This occurs because the stochastic term in the household-level demand specification is the sum of the stochastic terms associated with the K appliance utilization equations (8). Specifically, from equations (8) to (10), the variance of the household-level stochastic term is a function of the appliances owned:

$$\begin{aligned} \operatorname{var}(\varepsilon) &= \sum_{j=1}^{K} \sum_{k=1}^{K} d_j d_k \operatorname{cov}(\varepsilon_j, \varepsilon_k) \\ &\equiv \sigma(d_1, d_2, \ldots, d_K)^2. \end{aligned} \tag{11}$$

We think of the appliance-level stochastic terms as reflecting households' idiosyncratic tastes for utilizing appliances. A variety of behavioural considerations then suggest that the covariance terms entering (11) will tend to be positive, so that the variance of the household-level stochastic term will increase with the number of appliances owned.

From an econometric perspective, equation (11) is a simple model of group-wise heteroscedasticity in which the "group" is a specific portfolio of household appliances. Normally, this would not be a major concern for estimating the parameters of a linear demand specification such as (10). When consumers face nonlinear prices, however, the variance of the household-level stochastic term affects the likelihood that a consumer will fall on one tariff segment or another. This can be seen immediately from equation (6), where (the root of) the variance term, σ, enters the conditional expectation function and the tariff segment probabilities. The heteroscedastic variance of unobserved tastes thus affects expected consumption calculations and estimation of all the demand parameters.

4. ESTIMATION DETAILS

The foregoing discussion suggests a straightforward, albeit nonlinear, least-squares procedure for estimation. This is to choose as estimates the values of the unknown parameters that minimize the difference between the observed and expected annual consumption outcomes. Unfortunately, for some realizations of the data (including ours), the conditional expectation function (6) may be nearly flat with respect to σ near its true value. In essence, the first moments of the sample may contain too little information to estimate the variance components in (11) accurately. To resolve this problem, it is necessary to incorporate additional information into estimation.

We employ a generalized method of moments (GMM) procedure based on first- and second-moment differences between observed and expected annual consumption:

$$\begin{aligned} u_1 &= x^a - h_1(\mathcal{W}, \theta) \\ u_2 &= (x^a)^2 - h_2(\mathcal{W}, \theta) - 2h_1(\mathcal{W}, \theta)\,(x^a - h_1(\mathcal{W}, \theta)), \end{aligned}$$

present some evidence on this issue for gas vs. electric home heating systems. In earlier work we attempted to account for this possible endogeneity in a homoscedastic model (where the household-level error did not depend on the appliances owned; cf. equation (11)). For appliance instruments we used 30-year averages of local weather data. The results from this model did not differ noticeably from an un-instrumented homoscedastic model.

where $h_r(\mathcal{W}, \theta) = E[(x^a)^r | \mathcal{W}]$ denotes the r-th conditional moment of annual consumption, θ the unknown parameters to be estimated, and $\mathcal{W}$ all observable variables influencing the household's annual consumption. The second equation bases inference on the centred second moment of annual consumption.[17] Let β denote the demand parameters from (10) and ξ a vector of variance terms from (11), so $\theta = (\beta, \xi)$. Since optimal instruments in this setting involve (covariance-weighted) derivatives of the conditional moments h_1 and h_2, we set

$$z_1(\mathcal{W}, \theta)' = \nabla_\beta\, h_1(\mathcal{W}, \theta) \qquad \text{and} \qquad z_2(\mathcal{W}, \theta)' = \begin{bmatrix} \nabla_\beta\, h_2(\mathcal{W}, \theta) \\ \nabla_\xi\, h_2(\mathcal{W}, \theta) \end{bmatrix},$$

and base estimation on the orthogonality conditions $E[z_r' u_r] = 0$, $r = 1, 2$.[18] Note that the gradient of h_1 with respect to the variance parameters is excluded from the instruments, for the sample analogue contains no useful information (it is essentially singular—this is the reason the variance parameters are not identified by (6) alone).[19]

The functional form of $h_1(\mathcal{W}, \theta)$ is given by (6) and (7). The functional form of $h_2(\mathcal{W}, \theta)$ is derived similarly, and involves the second moment of the truncated normal distribution. In doing so, an additional complication arises due to temporal aggregation of consumption. While computing h_1 involves only the mean and variance of the stochastic term ε in the underlying monthly demand specification, evaluating h_2 requires an assumption about the correlation of ε over time. We assume that the value of ε in the household's demand specification (10) is independent from month to month. Jointly estimating an autocorrelation structure for the 12 monthly unobservables appears impractical with annual consumption data.

Estimation sequentially minimizes the metric $||A\, u(\theta)||^2$, where A is a weighting matrix held fixed during each minimization, and $u(\theta)' = [u_1(\theta)'\ u_2(\theta)']$ is the $2n$-vector of "stacked" first and second conditional moment differences for all n households. The matrix $A = \tilde{R}\, \tilde{Z}' D$, where D is a diagonal matrix containing the survey sampling weight for each observation, $\tilde{Z}$ the matrix of instruments evaluated at an initial (consistent) estimate of θ, and $\tilde{R}$ the (Cholesky) root such that $\tilde{R}'\tilde{R} = [D\tilde{Z}'\tilde{\Omega}\tilde{Z}D]^{-1}$. Here $\tilde{\Omega}$ is the true covariance function matrix $E[u(\theta)u(\theta)' | \mathcal{W}]$, evaluated at the initial estimate of θ. These covariance functions are directly computable (the non-zero elements being the second through fourth conditional moments of annual consumption), and we use their analytic expressions in estimation.

To obtain final parameter estimates, we iterated minimization of the GMM distance metric six times using successive updates of the matrix A. Full optimization required approximately three minutes on a 2·0 GHz computer, with 270 moment equations and 212 estimated parameters. Numerical optimization was performed using an efficient trust-region subspace minimization algorithm (Nocedal and Wright, 1999) and implemented in Matlab.

5. DATA AND EMPIRICAL SPECIFICATIONS

We estimate the model using data from the *Residential Energy Consumption Survey* (RECS). The RECS is conducted every three to four years by the U.S. Department of Energy to collect information on household appliances and energy use. The survey is a nationally representative

17. Centring (via the cross-product term $-2h_1(x^a - h_1)$) considerably improves sampling precision: if $(x^a)^2 > h_2$ then the cross-product term tends to be negative, and conversely if $(x^a)^2 < h_2$, which reduces the sampling variance of u_2.

18. It may be verified by direct analysis that these instruments preserve a unique solution for θ to equations $E[z_r' u_r] = 0$, $r = 1, 2$, provided that the variance function $\sigma(d_1, d_2, \ldots, d_K)^2$ is bounded away from zero.

19. In estimation we use a re-parameterization of the variance function (11) that facilitates estimation but at the cost of increasing the number of parameters. Estimation is easier because the re-parameterized GMM objective function is orthogonal in each of the 154 variance parameters. This re-parameterization imposes positive definiteness but otherwise places no restrictions on the covariance matrix in (11).

probability sample of households, with representative subsamples for several large states. We use the California subsamples of the 1993 and 1997 survey waves. Together they provide information on 1307 California households.

The survey is conducted through in-home interviews. Interviewers inventory the household's appliances, assess physical characteristics of the residence, and collect demographic information. The survey also includes weather data (heating and cooling degree-days) for each household, which are obtained from the nearest National Weather Service (NWS) station during the survey year. Each household's metered energy consumption data are collected by the survey directly from its electric utility. Further details about the RECS data and survey design are available in EIA (1994, 1996).

The appliance information, representativeness, and quality of the consumption data make the RECS particularly valuable for analysing household electricity demand. There are, however, two noteworthy shortcomings of the RECS data. The first is that the RECS public-use files only provide *annual* household electricity consumption and expenditures, as noted in Section 2. The second shortcoming pertains to the limited electricity tariff information available in the survey. Inadequate pricing data are a first-order problem for many previous studies of electricity demand and for other researchers using the RECS. Our considerable efforts to rectify this problem merit a brief digression here.

5.1. Prices

During the sample period most California households faced an increasing two-tier electricity price schedule each month, such as the one depicted in Figure 1. These schedules vary by service provider, climate zone, household heating system, household income, and season. For example, the state's largest utility, Pacific Gas and Electric (PG&E), had 72 variants of its standard residential rate schedule in effect during 1993 and 1997. A similar structure applies to the state's other major utilities.

The RECS data provide two summary price measures for each household. The first is the household's annual average electricity price, in cents per kilowatt-hour. The second is the local electric utility's annual average revenue per kilowatt-hour sold to all its residential customers. Either of these price measures unfortunately presents problems for modelling electricity demand at a disaggregate (household) level. As noted in Section 2, the first of these two price measures is endogenous (it rises with consumption) and bears a complex relation to the household's monthly use. The second, utility-level average price, while putatively exogenous, will typically mis-measure the actual marginal price faced by a household. Either summary price measure could therefore be expected to provide poor information regarding the marginal price facing the household each month, and thus biased price elasticity estimates.

To address these shortcomings, we developed a procedure for matching each observation in the RECS with the complete rate schedule facing the household. The data this requires that are not provided in the RECS are each household's utility and its utility-designated climate zone. To determine these, we exploit three types of information in the RECS about the household: the local utility's average electricity price, the availability and price of natural gas, and the weather information. The weather data provide considerable information regarding where in California's diverse climate zones each household is located. The utility-level electricity and natural gas price data then help pinpoint the household's service provider.

To match each RECS household to its utility and climate zone, we first used maps of utility service areas to assign each of the approximately 240 NWS stations in California to one (or two adjacent) utility service territories. We then collected the local average electricity and gas prices for each service territory in the state. These weather and price data are the same primary data series used by the RECS and included with each household in the survey. We then determine each household's utility and climate zone by matching the household's information in the RECS with the known average price and weather data for each utility and NWS station in California.

The remaining information necessary to determine a household's specific rate schedule (namely, the household's income and its home heating system) are directly available in the survey. We also used the RECS's electricity expenditure data to determine which eligible low-income households are actually participating in their utilities' low-income electricity tariff programmes. To complete the procedure, we manually compiled the complete 1993 and 1997 electricity tariff books for each California utility, from filings archived at the California Public Utilities Commission public records library and direct contact with municipal utilities' tariff departments. In the end, the 1307 California households in the RECS sample were matched to 189 distinct rate schedules.

Table 1 provides some information on how well this matching procedure performs. As the survey is a stratified probability sample of California households, we expect (and find) reasonable agreement between what the utilities report as their number of residential accounts and the number of households implied by the survey. For the five largest utilities (which serve 93% of California households), the implied geographic distribution of RECS households by utility is quite close to that reported in the utilities' regulatory accounting data. The most notable deviations occur for the two smallest investor-owned utilities, Sierra Pacific and PacifiCorp, which serve sparsely populated mountainous northern and eastern areas of the state. We believe that the stratification design and a special segment of the RECS that oversamples low-income households may account for their overrepresentation.[20]

5.2. *Appliance demand specifications*

Our monthly appliance demand specifications are based on prior empirical research that has studied households' appliance use decisions. Principal sources are the EPRI/REEPS model described in LBL (1995) and the EIA Residential End-Use Model, EIA (1995). We model end-use electricity demand using eight distinct appliance categories: (1) baseline electricity use; (2) electric space heating; (3) central air conditioning; (4) room air conditioning; (5) electric water heating; (6) swimming pools; (7) additional refrigerators and freezers; and (8) other appliances. The baseline category accounts for the electricity consumption of appliances that are universally owned, such as the (first) refrigerator and lights. This category also implicitly includes consumption attributable to any unspecified electrical appliances below the resolution of the RECS survey (such as electric clocks, irons, hair dryers, and the like). Appliance categories two through six are energy-intensive end uses that previous research indicates exhibit some utilization price elasticity (EPRI, 1989). The final category includes less energy-intensive household appliances. A description of all appliances entering the model is provided in Table A1.

Different factors influence appliance-level electricity demand in each category. In particular, we estimate separate price and income effects for each of the first six categories. The remaining appliances are assumed to have a common price effect, as previous studies indicate most of these (refrigeration, cooking, clothes dryers, etc.) exhibit no significant electricity price elasticity. Demographic and other explanatory variables entering the model are defined in Table A2. Demographic characteristics of households are assumed constant during the survey year; the

20. We are grateful to U.S. Energy Information Administration analysts for lengthy discussions on these RECS sampling issues. One unresolved issue is the RECS sampling weights imply 350,000 more California households with electricity service than comparable figures in California utilities' regulatory accounting data (this is evident in the bottom line of Table 1). In addition, the survey's cluster sampling procedure will generally yield uneven coverage of smaller utility service areas.

TABLE 1

Average price and number of households for California electric utilities

	Average residential rate in 1993[a] (cents per kWh)	*Number of households*		*Per cent of households*

monthly varying covariates in our specifications are the price schedules and the weather data.[21] All monetary variables are normalized to real (June 1993) prices, using the CPI-U series for California's three consolidated metropolitan statistical areas.

6. RESULTS AND IMPLICATIONS

6.1. Estimates and marginal effects

Table 2 presents the model's estimated marginal effects for the principal variables of interest. Table entries show the effect of a one unit increase in each explanatory factor on monthly kilowatt-hour consumption of each specified appliance. We compute marginal effects separately for each household (using the gradient of its conditional expectation function (6)), and then average across households using the RECS sampling weights. These are interpretable as the mean marginal effects in the population, conditional on ownership of the indicated appliance. Raw demand parameter estimates are reported in Table A3. The fitted model has a mean square error of (2352 kWh/year)^2, which is approximately one-third of the sample variance of consumption.[22]

21. In addition to the specifications evident in Table A3, we imposed a constraint that electricity consumption for space heating and cooling is zero during the summer and winter months, respectively. To accommodate the varied heating and cooling season lengths for different regions and elevations in California, this was implemented via a minimum (one per day) degree-day threshold for the use of these appliances.

22. Hansen's over-identification test statistic is 76·9, which under simple random sampling has $p = 0{\cdot}05$ (df $= 58$) asymptotically. The RECS is not based on simple random sampling, however. Its multi-stage sampling design implies the actual critical value of this test statistic will be larger (possibly much larger) than its nominal counterpart. We take an alternative formal approach to testing model fit in Section 7, using standard errors adjusted by the survey's design

TABLE 2

Estimated marginal effects (asymptotic standard errors in parentheses)

Explanatory variable	*Effect on kWh consumed per month for:* [a] Baseline use	Elec. space heating [b]	Central air cond. [c]	Room air cond. [c]	Elec. water heating	Swimming pool
Price (cents/kWh)	0·4 (3·7)	−37·8 (14·8)	−22·5 (21·3)	−63·4 (31·1)	−34·0 (9·5)	−27·5 (18·4)
Income ('000 $)	0·4 (2·3)	16·2 (13·0)	9·1 (10·6)	21·6 (20·8)	−32·8 (7·5)	6·3 (9·8)
No. of members	18·0 (3·3)	−7·9 (20·3)	−38·6 (16·3)	−52·1 (19·9)	47·5 (10·6)

Rural location	31·4 (25·1)					

(Effects of additional appliances are shown in Table A4)

[a] Estimated change in monthly appliance electricity consumption associated with a unit increase in the explanatory variable, *ceteris paribus*. The marginal effects shown are estimated population means, conditional on appliance ownership.
[b] Heating-season months only.
[c] Cooling-season months only.

The signs and magnitudes of the estimates in Table 2 generally agree with prior studies, although there are a few exceptions.[23] The estimated price effects vary substantially across appliances. The smallest effect is associated with baseline use, and is effectively zero. All other appliance price sensitivities are of considerable practical significance. For example, the −27·5 estimate for price and swimming pools in Table 2 implies that a one cent per kilowatt-hour (kWh) increase in the marginal price would reduce a household's annual utilization of pool pumps and motors by approximately 330 kWh per year, which is 15% of a pool's typical electricity use. The

efficiency ratios to account for its complex sampling design.

23. For example, the negative coefficients on income and on the number of rooms in the water heating specification. We suspect this may be due to confounding from unobserved variation in water heater energy efficiency, which is likely to be considerably higher in newer (larger) homes in California. The negative coefficients on the number of household members and space cooling are also of unexpected sign, and may be attributable to an omitted (positive) influence of householder age on space cooling demand.

TABLE 3

Price and income elasticities for California households

Mean elasticities of electricity demand[a]	Price: GMM method	Price: OLS method	Income: GMM method	Income: OLS method

[a] Annual elasticities (see text and Appendix B).

price effects for major appliances providing space heating, cooling, and water heating services differ from one another considerably, both in absolute terms and relative to typical consumption for each appliance (see Table A4).

By contrast, the income effects are mostly statistically insignificant and negligible as a practical matter. This is not entirely surprising, given that our analysis is conditional on households' appliance stocks. To the extent that income affects electricity consumption, it is evidently manifest through households' choices of appliances rather than through utilization behaviour. These results are consistent with prior studies' findings of low-to-negligible appliance utilization income elasticities at the household level (*e.g.* Parti and Parti (1980) and Dubin and McFadden (1984)).

Details on specific appliance-level consumption estimates are provided in Appendix A and Table A4.

6.2. Price elasticities

Table 3 presents estimated average annual household price and income elasticities. These elasticity estimates correspond to the percentage change in a household's annual electricity consumption resulting from a 1% increase in the marginal price (or household income) in each month of the year, holding the appliance stock fixed. We calculate demand elasticities separately for each of the 1307 households in the sample, and then average using the survey sampling weights. The elasticities shown in Table 3 are estimated population means for California households.

Before interpreting these numbers, it is important to note that with nonlinear tariffs there is more than one "price" involved in measuring the elasticity of demand. For example, one can calculate the elasticity of demand with respect to an increase in the intercept of the price schedule, with respect to the price of a specific tariff tier, or with respect to the consumer's marginal price. We present elasticity estimates based on the third of these interpretations, so as to reflect households' demand sensitivity on the margin. In doing so we recognize the fact that with multi-part tariffs, changing a consumer's marginal price may alter consumption within the current tariff segment or induce a discrete jump to a different price tier. Our elasticity calculations explicitly account for this possibility, using methods described in Appendix B.

We estimate the mean annual electricity price elasticity for California households to be −0·39. Previous studies of residential electricity demand data have estimated widely varying utilization price elasticities, ranging from nearly zero to about −0·6. These estimates reflect differences in the geographic regions examined, as well as considerable variation in data quality and statistical techniques. Studies conducted by electric utilities, which often have higher-quality data, tend to obtain price elasticities within a narrower range of −0·15 to −0·35 (EPRI, 1989). Our results with the California RECS data fall at this set's upper end, but are close to the −0·35 estimate contained in a much earlier Rand Corporation study of Los Angeles-area households by Acton, Mitchell and Mowill (1976).

It is useful to compare our estimates to those using more traditional estimation methods. The second column in Table 3 shows the elasticities obtained if we ignore the simultaneity of price and quantity under nonlinear pricing and simply perform OLS using the household's average price. The resulting mean price elasticity estimate is +0·16, which has the wrong sign. Such large biases are typical when simultaneity is ignored in electricity demand studies, for the simple reason that there is wide (cross-sectional) variation in demand but relatively limited variation in the price schedules. OLS techniques using the consumer's average or marginal price therefore tend (in essence) to fit the average slope of the price schedule. Similar biases are noted in Dubin (1985) and Maddock *et al.* (1992).

Additional regressions that use other summary price measures appearing in the literature (*e.g.* the midpoint of the two tiers or utility-level average prices) yield elasticity estimates of the correct sign, but much smaller in magnitude than the GMM results using the complete rate schedule. For example, estimates obtained using OLS with the (statistically exogenous) utility-level average price measure in the RECS yield a mean household price elasticity of −0·28.[24] This estimate is consistent with the bias toward zero that one would expect due to this proxy's mis-measurement of the consumer's actual marginal price. It also suggests an explanation for why our GMM estimates imply somewhat more price-elastic behaviour than many earlier studies' (particularly the utility-conducted studies noted above), in that most prior work treats tariff structure information in either an *ad hoc* manner or not at all.

Heterogeneity in price sensitivity. The disaggregate data also reveal considerable and meaningful heterogeneity in households' price and income elasticities. As noted previously, the model permits households' price and income elasticities to vary across households not just with their consumption level, but also with their appliance holdings. Table 3 illustrates the marked differences in demand elasticities for households with different heating and cooling systems. Households with electric space heating or air conditioning exhibit a much higher electricity price elasticity than households without such systems. Households that do not use electricity for either of these purposes have an estimated mean price elasticity very close to zero. This heterogeneity is consistent with the limited prior evidence on electricity price elasticity variation across households (*e.g.* Dubin, 1985). As a practical matter, it suggests that there are effectively two "types" of households with respect to electricity demand behaviour: those who use electricity for space heating or air conditioning and exhibit some electricity price elasticity, and those who do not and are price insensitive.

Further information about the heterogeneity in households' demand elasticities is provided in Figure 2. This histogram of the sample households' price elasticities is constructed (using the survey weights) to represent the distribution for the California population. The point-mass at zero

24. Price elasticity differences of seemingly small amounts (*e.g.* −0·28 vs. −0·39) are economically quite important in electricity markets. Assuming residential demand is too inelastic by this difference of −0·1 when increasing the marginal rate by (say) three cents per kWh would overestimate annual revenue for California's larger utilities by approximately 75 million dollars.

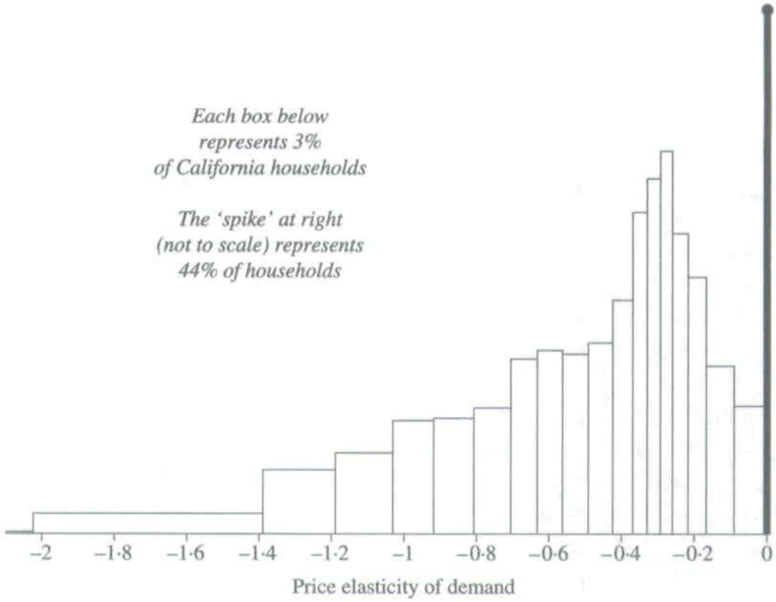

FIGURE 2
Estimated distribution of California households' electricity price elasticities

indicates that 44% of California households exhibit no short-run demand sensitivity to changes in the marginal price of electricity. This segment of the population is primarily households that own no major electric appliances other than a refrigerator, and whose minor appliances fall within the inelastic "baseline use" category of the model. The expected fraction of households whose demand curves cross their price schedules in the "gap" between the two price tiers is 1–2% each month. Thus, very few households have a locally zero estimated price elasticity due only to the discontinuity in the price schedule.

The striking feature of Figure 2 is its highly asymmetric, negatively skewed shape. This pattern indicates that most households will alter their electricity consumption very little in response to a price change. A small fraction of households, however, are actually elastic demanders (roughly 1 in every 8 families) and would react with large changes in their electricity use. This has noteworthy implications for the welfare effects of electricity price changes, inasmuch as most of the dead-weight welfare losses from a price increase would evidently be borne by a fairly small share of the consumer population.

Where a household is located in this distribution is related to its income and other demographic characteristics. Table 4 summarizes household electricity price elasticities by income and consumption levels. How price elasticities vary with household income (in the cross section) is of interest because regulatory commissions provide subsidized tariffs to low-income households, and are at times concerned with the consumption incentives of these subsidies. The conventional wisdom is that households with lower incomes are more sensitive to energy prices than households with medium-to-high incomes. The results in the top half of Table 4 are consistent with this view, although the magnitudes of these differences are not dramatic.

The lower half of Table 4 indicates how household price elasticities vary with the amount of electricity the household consumes. This relationship is of interest because the aggregate consumption and revenue effects of a tariff change depend upon how elasticities vary across the different tiers of the price schedule. Somewhat surprisingly, we find that elasticities are lower

TABLE 4

Price elasticities by household income and electricity consumption

Quartile	Quartile range	Price elasticity[a] GMM method	Price elasticity[a] OLS method
By household annual income level:[b]			
1-st	Less than $18,000	−0·49	+0·15
2-nd	$18,000 to $37,000	−0·34	+0·17
3-rd	$37,000 to $60,000	−0·37	+0·14
4-th	More than $60,000	−0·29	+0·17
By household annual electricity consumption:			
1-st	Less than 4450 kWh	−0·46	+0·37
2-nd	4450 to 6580 kWh	−0·35	+0·04
3-rd	6580 to 9700 kWh	−0·32	−0·00
4-th	More than 9700 kWh	−0·33	−0·08

[b] Approximate California household income quartiles, in 1998 dollars.

for households that use high amounts of electricity, despite the fact that households with energy-intensive electric space heating/cooling systems have much greater electricity price sensitivity *ceteris paribus*. This inverse relationship reflects both a weak correlation between household income and ownership of electric space heating/cooling systems, and the fact that households tend to substitute toward more price-inelastic electricity uses as income rises. Thus, from an economic efficiency standpoint, the welfare cost of raising a given amount of revenue will be minimized if the marginal price changes are disproportionately larger for the highest-demand consumers.

Further results along these lines using different data are examined in Reiss and White (2003).

7. VALIDATION: THE 1998 PRICE CHANGES

Our empirical results rest in part on the appliance demand specifications and error distribution assumptions of the model. Because we must aggregate over appliances and over time to match the consumption level of the data, these appliance demand specifications are not testable directly. In this section we examine the model's validity using both within- and out-of-sample tests.

7.1. Within-sample fit

For purposes of interpreting the out-of-sample test below, it is useful to first examine the representativeness of the RECS consumption data and in-sample model predictions. Because electric utilities are subject to extensive regulatory reporting requirements, there exist comprehensive aggregate data on utilities' actual sales and number of customers. In principle, averages from these data will differ from their counterparts for the RECS households by amounts attributable to the survey's sampling error.

Some evidence on this issue is provided in Table 5. The first numerical column in Table 5 presents actual electricity consumption per household for California and its four largest utilities. The second column presents the corresponding mean electricity consumption for the RECS

TABLE 5

Within-sample predicted and actual consumption

Electricity consumption per household, in kWh	Actual[a]	Sample data: Sample mean	Sample data: Standard error[b]	Sample data: Actual error	Estimated model: Predicted mean	Estimated model: Average within-sample error
Pacific Gas & Elec.	6531	5796	258	+735	5899	+103
Southern Calif. Edison	6238	6063	291	+175	5961	−102

Los Angeles Wtr. & Power	5261	5113	454	+148	4867	−246
All California	6355	6007	157	+348	6010	+3

[a] Weighted average of the total residential sales (in kWh) divided by the number of residential accounts in each of 1993 and 1997, as reported by each utility. Source: U.S. Dept. of Energy Form EIA-861 (1993, 1997).

[b] Standards errors shown account for the multi-stage sample design of the RECS (see EIA, 1994).

sample households along with the standard error of the survey. For the state as a whole, Table 5 implies that the RECS sample under-represents actual household electricity consumption by slightly more than two standard errors. We also find that the RECS data understate average household consumption for each of the state's four largest utilities, although by sometimes less than two standard errors.[25]

The final columns compare the model's predictions to these actual and sample consumption averages. Since the model is fitted to the RECS data, the difference between the observed and predicted averages represents within-sample error. Although our model is nonlinear, the average within-sample error for the full sample is essentially zero. As with the raw sample data, however, the estimated model under-predicts actual consumption for each utility and the state overall. This is not entirely surprising, given that the model can at best capture the behaviour of the sample to which it is fitted. We conclude that while the RECS sample appears to understate actual household consumption in California, the model does reasonably well (*i.e.* within a few per cent) at fitting the sample data for each utility.

7.2. *Out-of-sample tests*

In January 1998, shortly after the end of our sample data, California's three largest investor-owned utilities reduced the price of residential electric service by 10%. This price change, by virtue of its magnitude and exogeneity to the household, provides a unique opportunity to evaluate the model's out-of-sample accuracy. We also account for the El Niño Pacific weather disturbance that occurred in 1998 and 1999, which changed California's weather patterns substantially.

Ideally, we would prefer to evaluate the model using within-household differences in predicted and actual consumption between 1997 and 1998 (*i.e.* a matched-pair test). Unfortunately, due to the triennial (and non-longitudinal) nature of the RECS, we do not have data on actual consumption after 1997 for the sample households. Instead, we base inference on

25. There are other reasons why the *utility-specific* averages might differ between the RECS and the actual (regulatory accounting) data. First, while the RECS is designed to generate a representative sample of households at the state level, the sampling scheme is not designed to produce representative samples within each utility's service territory. Second, the household-utility matching procedure we use to obtain rate schedules (in Section 5) introduces potential misclassification error. The difference in state-level average consumption between the RECS and the regulatory accounting data is not subject to these caveats, however.

TABLE 6

Out-of-sample prediction tests for 1998 and 1999

Utility electricity sales per household, in kWh	Actual[a]	Predicted	Difference	Std. error	Prob.[b]
		Panel A: 1998

[b] Approximate probability of a difference between actual and predicted at least as large (in magnitude) as observed, under the model.

comparisons to the average household consumption reported in California utilities' regulatory accounting data for 1998 and 1999.

To implement a formal test we first extended the actual weather series used in the model through 1998 and 1999. We also collected the exact form of the tariff changes implemented in 1998 and 1999 for each RECS household.[26] We then use the model to predict what the RECS households would have done in 1998 and 1999, given the price change and weather conditions that occurred, and aggregate these responses to the utility level.

Table 6 compares these out-of-sample predictions to actual residential electricity consumption for California's four largest utilities in 1998 and 1999. The second-to-last column provides estimated standard errors for the difference between the actual and predicted consumption averages. These standard errors account for both the non-sampling variance in future consumption outcomes under the model, and the sampling error associated with the RECS multi-stage design.[27] The final column reports the (two-sided) probability of observing a difference at least as large as that shown, under the maintained assumptions of the model. Small p-values constitute evidence against the validity of the model.

As the within-sample results foreshadowed, the model continues to under-predict average consumption in 1998 and 1999. For three of the four utilities in each panel, however, the observed differences from the model's predictions are within the bounds of what may be ascribed to chance by conventional standards of statistical significance. The smallest p-values, for Pacific Gas and Electric in 1998 and 1999, are attributable to the particularly acute under-representativeness (relative to sampling error) of the RECS households' consumption data for

26. The January 1998 price decrease amounted to lowering each tier of the household's price schedule by 10%. The actual marginal price change thus depends upon the household's particular rate schedule. There was also a separate price increase for households served by the Los Angeles Department of Water and Power in 1999, which shows up as a notable decline in consumption for Los Angeles households between 1998 and 1999.

27. Since we have a nonlinear model and the RECS uses a multi-stage sampling design, the standard errors for this test are approximate. We use a linear approximation (delta) method to estimate the variance of average predicted consumption under simple $(1/n)$ random sampling, and then inflate the result by the design efficiency ratio of the RECS consumption series (about 1·4) to get the standard errors in Table 6. This method and related techniques are discussed in Skinner, Holt and Smith (1989).

this utility. Interestingly, for three of the four utilities in each panel, the model's average error (relative to actual) is smaller for the out-of-sample years of 1998 and 1999 than it is for the within-sample years reported in Table 5. On that basis, the model appears to deliver reasonable predictions for how California households respond to electricity price changes.

8. ANALYSING PROSPECTIVE TARIFF DESIGNS

An important feature of the model developed above is that it can be used to evaluate, on a prospective basis, the effects of complex price schedule changes. For a variety of practical reasons, regulatory agencies are often reluctant to authorize randomized-assignment pricing experiments as a means to evaluate major tariff changes. Thus, counter-factual simulations based on econometric models become the analytic method of choice. The accuracy of these simulations is a matter of considerable practical interest, inasmuch as tariff changes for electricity can affect billions of dollars in consumer expenditures.

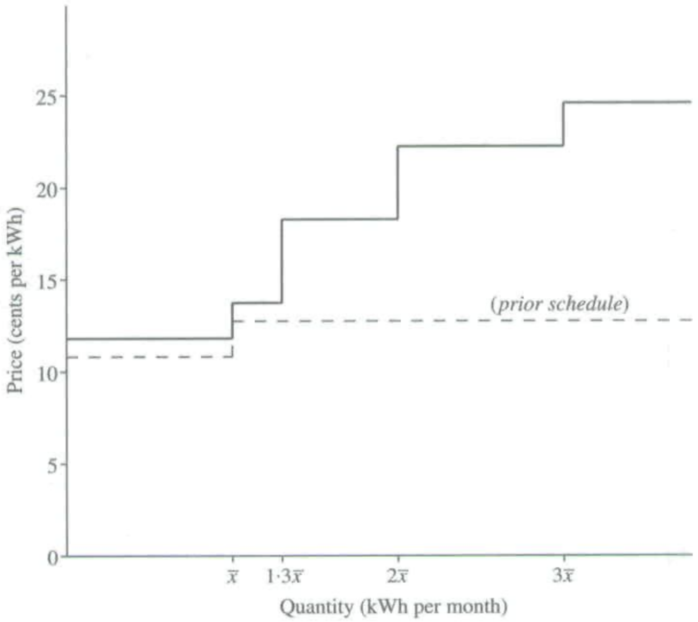
In this section, we provide consumption and expenditure estimates for a complex tariff design being implemented in California. Following a financial crisis facing that state's utilities in the spring of 2001, the California Public Utilities Commission approved new tariff structures for the state's two largest utilities. The new multi-part tariff structure for residential electric service is shown graphically in Figure 3. Under this five-tier design, the household inherits from its prior (two-tier) tariff a monthly reference quantity, $\bar{x}$. The first $\bar{x}$ kilowatt-hours of monthly electricity consumption are then billed at one price per kilowatt-hour, the next $30\% \times \bar{x}$ are billed at a higher price, and so forth as indicated in Figure 3. The reference quantity $\bar{x}$ and the specific tier prices vary based on the utility, the season, the household's climate zone and home heating system, and other factors.

This novel pricing system is intended to achieve several objectives. First and foremost is to raise additional revenue for the state's utilities. Second, the new tariff is intended to promote energy conservation, particularly among higher-demand consumers. Third, there is a distributive objective underlying this tariff design. Electricity is a necessary good (in the sense that its budget share declines as household income rises), so a uniform increase in the price of electricity can be quite regressive. By raising marginal prices more for higher levels of consumption, regulatory authorities hope to attenuate this regressivity and minimize expenditure changes for lower-income households.

Because the five-part tariff is unprecedented in historical consumption data, there is no way to extrapolate how well this new system would achieve these objectives using descriptive (*i.e.* reduced-form) econometric methods. Rather, predicting aggregate demand requires explicitly modelling consumer choice behaviour under the new tariffs. To do so, suppose j indexes the five tiers in Figure 3, p_j is the marginal price on tier j, and $\bar{x}_j$ is the j-th-tier upper boundary. Set $x_j = x(p_j, y_j, z, \varepsilon; \beta)$, where y_j denotes the household's income plus the cumulative infra-marginal price discount applicable in tier j. Conditional on observable household characteristics, the expected value of monthly household consumption is then

$$E(x^* \mid \cdot) = \sum\nolimits_{j=1}^{5} P_\varepsilon(\bar{x}_{j-1} < x_j < \bar{x}_j) \cdot E_\varepsilon(x_j \mid \bar{x}_{j-1} < x_j < \bar{x}_j) + \sum\nolimits_{j=1}^{4} P(x_{j+1} < \bar{x}_j < x_j) \cdot \bar{x}_j \tag{12}$$

using the conventions $\bar{x}_0 = 0$, $\bar{x}_5 = \infty$, and P_ε the distribution of ε given the observables. The first sum is the contribution to expected consumption conditional on demand crossing the price schedule on one of the five steps, and the second sum is the contribution conditional on demand crossing the price schedule in one of the "gaps" between the steps. As before, this



Notes: The reference quantity, $\bar{x}$, varies across households and seasons. The rates depicted above are for the most common residential tariff schedule for this utility. The prior schedule shown applied from 1998 through 2000.

FIGURE 3

A five-tier price schedule Southern California Edison, Residential Electric Service

amounts to a probability-weighted average of expected demand within each segment of the new tariff schedule. Stated in behavioural terms, the consumer sorting-on-the-unobservables problem that occurs with multi-part tariffs must be addressed not only in demand estimation, but also when predicting consumption at new prices.[28] Such nonlinearities are why the aggregate impacts of a new tariff design depend, sometimes delicately, upon the heterogeneity in consumers' price elasticities across the population.

We use equation (12) and the estimated demand model to evaluate a five-tier tariff system adopted by the California Public Utilities Commission in May 2001. With little prior analysis, this system was implemented the following month for approximately 7·8 million households served by the Pacific Gas and Electric Company and the Southern California Edison Company. We use these utilities' tariff books to identify the terms of the new tariff applicable to each household in the RECS sample. We also evaluate these tariff changes for "normal" weather conditions, using 30-year average degree-days from the NWS station located nearest each household. The tier selection probabilities in (12), which depend upon both the household and its particular tariff schedule, are evaluated using the normality assumption and household-specific variance estimate from the econometric model. We evaluate the expected consumption equation

28. In particular, equation (12) differs from what one obtains by simply intersecting the household's estimated demand curve (assuming ε to be zero) and the new price schedule. That technique implicitly treats the tariff segment selection probabilities in (12) as either zero or one, and ignores the conditional expectation adjustment for ε in each tariff segment. Unless the variance in the household's future consumption (given the observables) is in fact zero—a highly unlikely circumstance—such a technique will systematically misestimate consumption under a new price schedule.

TABLE 7

Household consumption and expenditure changes with five-tier tariff schedules (all monetary amounts in constant 1998 dollars)

Means per household[a]	All households	By income quartile[b] 1-st	2-nd	3-rd	4-th
Consumption (kWh/year)					
With 2 tiers (1998)	6196	5524	6299	6330	7455
With 5 tiers	5578	4987	5677	5519	6637
Change (%)	−10·0	−9·7	−9·9	−9·7	−11·0
Expenditures ($/year)					
With 2 tiers (1998)	718	633	734	734	873
With 5 tiers	897	770	921	925	1120
Change (%)	24·8	21·6	25·4	25·9	28·3

separately for each of the 1307 households in the RECS sample, and average these predictions using the survey sampling weights. A similar formula and procedure is used to estimate each household's (expected) expenditures under the new tariff.[29]

Table 7 provides estimates of average household electricity consumption and expenditures under the new five-tier tariffs. For comparison, we also show the values obtained using the prior two-tier tariff schedules in effect from 1998 through 2000. The first numerical column presents estimated population means for all the 7·8 million affected households. The results indicate their average (and aggregate) annual electricity consumption would be approximately 10% lower under the new five-tier tariff system than under the preceding tariffs over a normal weather year. The corresponding increase in annual household electricity expenditures is approximately 25%, or $179 per household (in 1998 dollars). To put this in some perspective, $179 is 8% of the average 1998 state personal income tax liability per household in California.

Our expenditure results are considerably lower than the official estimates of the California Public Utilities Commission. That agency predicted the increase in the two affected utilities' total residential electric revenues would be approximately $1·8 billion annually, or $228 per household. The difference between these two estimates can be explained largely by differences in the treatment of demand elasticities. In particular, the Commission uses a "static scoring" method for predicting the revenue change associated with a new rate schedule design. This amounts to assuming that each consumer's annual demand is completely price-inelastic, so that expenditure changes can be predicted by applying the old and new tariff schedules to the same consumption data. Inasmuch as consumers do exhibit some demand elasticity, this method overestimates revenue associated with the higher tariff structure.

Since the model we employ is estimated with survey data, we have information on individual households' income levels that can be used to examine the distributional consequences of tariff changes. This issue has not been examined quantitatively in the state regulatory agency's tariff

29. Note that approximately 10% of households participate in a low-income tariff programme that is exempt from the new tariff designs. These households appear in our sample, and our predictions for them use their (unchanged) tariffs. The predictions do not account for changes in an eligible non-participating household's incentive to apply for this programme, however.

models, as their analyses rely upon utilities' billing data that do not include income information. The additional columns in Table 7 report the model's predictions for average consumption and expenditures by household income quartile. Not surprisingly, under either tariff electricity consumption and electricity expenditures increase with household income. What is interesting to note, however, is that in percentage terms the change in household electricity consumption between the new and old tariff systems is nearly constant across income quartiles. That is, the larger marginal price increases paid by households consuming higher quantities more or less exactly offsets the increasingly inelastic demand behaviour of households with higher incomes (see again Table 4).

A similar phenomenon is evident in the estimated expenditures. In absolute terms, however, the increase in expenditures across income quantiles does not rise nearly as fast as income. This implies, and can be verified directly in the unsummarized data, that the new tariff is (slightly) more regressive than the system it replaces. It is, however, considerably less regressive than a revenue-equivalent traditional uniform rate increase, whose distributional impacts California policy-makers have sought to avoid.

9. CONCLUDING REMARKS

The practical motivation for this paper arose from an acrimonious—and, we believe, poorly informed—debate over the consequences of major electricity price changes in California. Our objective is not to impugn the decisions ultimately made and examined here, however; rather, it is to show how more sophisticated empirical methods, in conjunction with detailed micro-survey data now available, can be productively harnessed to resolve *ex ante* the policy-making uncertainties that fuel such debates.

It is worth noting that substantively similar methodological issues arise in a variety of other markets. Regulatory pricing of local telephone service (a perennially controversial matter) and residential water use are leading examples. In those markets nonlinear pricing is quite common, and formal demand analysis is a largely accepted part of the price-setting process. The econometric issues addressed in this paper would appear particularly germane to those contexts. In a substantively different setting, there are close parallels between the analytic methods used here and the micro-simulation procedures commonly used to evaluate tax code changes. Specifically, the methodological aspects of implementing "dynamic" vs. "static" scoring techniques for tax revenue changes are precisely analogous to the modelling of consumers' demand elasticities in the tariff design analysis presented here.

Last, an interesting and useful extension of this research is the normative empirical analysis of nonlinear tariff designs. The methods employed above would appear to lend themselves readily to development of more economically efficient tariffs. For example, if the new five-part tariffs in California are efficient (by almost any criterion), it is by fortuity rather than by design. Despite a great deal of work in the theoretical literature on efficient nonlinear pricing schemes, there are as yet few (if any) detailed empirical studies. We leave this interesting issue a matter for future research.

APPENDIX A. APPLIANCE-LEVEL SPECIFICATIONS

A.1. Specification and parameters

A complete list of the variables entering the demand model is shown in Tables A1 and A2. The complete set of coefficient estimates are listed in Table A3. This table is organized so that each column contains the parameter estimates associated with an appliance category's electricity demand. These raw parameters are used to obtain the marginal effects in Table 2, as described in Section 6.

TABLE A1

Appliances entering electricity demand model

Mnemonic	*Appliance*	*Description*
	Primary electric space heating	1 if household has permanently installed electric space heating (electric furnace, heat pump(s), or wall resistance units)
	Central air cond.	1 if household has a central air conditioning unit
	Room air cond.	1 if household has room window/wall air conditioning units
	Electric water heat.	1 if household has an electric water heater
ELECCOOK	Electric cooking	1 if household has an electric oven and/or stove
ELECDRYR	Electric dryer	1 if household has an electric clothes dryer
FREEZER1	Separate freezer	1 if household has a separate (stand-alone) freezer
FREEZER2	Second freezer	1 if household has two (stand-alone) freezers
FRIDGE2	Second refrigerator	1 if household has a second refrigerator
CLTHWASH	Clothes washer	1 if household has an automatic clothes washer
DISHWASH	Dishwasher	1 if household has an automatic dishwasher
PORTHEAT	Portable space heat	1 if household has one or more portable electric space heaters
HOTTUB	Hot tub	1 if household has a hot tub with electric heating
POOL	Swimming pool	1 if household has a swimming pool
H2OBEDHT	Waterbed heating	1 if household has a waterbed with electric heating
MICROWV	Microwave	1 if household has a microwave oven
NTV	Number of TVs	Number of televisions in household

TABLE A2

Additional explanatory variables entering demand model

Mnemonic	*Variable*	*Description*
PRICE	Electricity price	Monthly electricity price, in 1993 cents per kilowatt-hour
INCOME	Household income	Average monthly household income, in thousand 1993 dollars
HDD	Heating degree-days	Monthly heating degree-days base 60 °F, in hundreds
CDD	Cooling degree-days	Monthly cooling degree-days base 70 °F, in hundreds
NROOMS	Number of rooms	Number of rooms in home (excluding bathrooms)
NBATHRMS	Number of bathrooms	Number of bathrooms in home
NMEMBERS	Number of members	Number of people in household
FRSIZE	Fridge/freezer size	Size of appliance, in cubic feet
ATHOME	At home	1 if someone is normally at home during the day
HUPROJ	Housing project	1 if household resides in a public housing project
APTBLDG	Apartment building	1 if household resides in an apartment building
RURAL	Rural location	1 if household resides in a rural location
URBAN	Urban location	1 if household resides in an urban location
YEAR97	Survey year 1997	1 if household data from 1997 survey wave

The model also includes 154 variance and covariance parameters (from equation (11)) not reported here. These indicate that the variance of household-level unobservable characteristics increases with appliance holdings, although it depends (in a complicated fashion) on the types of appliances owned by the household. Overall, the heteroscedasticity patterns sensibly reflect the enormous differences in potential energy consumption associated with different appliance portfolios.

A.2. Appliance consumption estimates

A useful feature of the fitted model is that it provides estimates of electricity use for each appliance. These are reported in Table A4. In addition to being of direct interest to energy analysts, these appliance-level consumption estimates provide a useful check on the model since they can be compared to independent estimates.

The first numerical column is the estimated proportion of California households that own particular appliances, based on a weighted average of 1993 and 1997 sample ownership frequencies in the RECS. The second column reports the model's prediction for the average annual electricity consumption of each appliance. These estimates are obtained

n.a. indicates an estimate is not available.

from the fitted appliance demand equations (8), then averaged across households (using the RECS sampling weights) so as to reflect typical values in the population of appliance owners.

The third column in Table A4 contains appliance energy consumption predictions from a model developed by the U.S. Energy Information Administration (EIA, 1995). The final column is from a Lawrence Berkeley Laboratory (LBL, 1997) meta-analysis of numerous residential appliance energy consumption estimates. These estimates are derived from a wide range of direct metering, engineering, and statistical studies of energy use in different areas of the U.S. Overall, there is general agreement between these prior studies and the model's results—perhaps surprisingly so, since the present model is not fit to utilization data for individual appliances. The principal difference occurs with heating, where the LBL survey reports a significantly higher number than we or the EIA do. This can in part be explained by the broader geographic coverage of the LBL analysis and the high sensitivity of heating energy use to climate differences.

APPENDIX B. ELASTICITY CALCULATIONS

This Appendix describes the method used to calculate the elasticity estimates reported in Tables 3 and 4. There are two complications that make calculating elasticity estimates more involved here than in conventional settings. The first is the temporal issue of how to calculate an annual elasticity of demand when the consumer may face varying (and unobserved) marginal prices over the course of the year. The second is the discontinuity problem—because the price schedule is discrete, a change in the consumer's marginal price can move consumption smoothly within a single tariff segment, shift the consumer off or onto the discontinuity between tariff segments, or yield no change in consumption at all.

Addressing the discontinuity problem first, write the optimal consumption for household i in month t using the equilibrium relation from equation (1):

$$x^*_{it} = x(p^*_{it}, y^*_{it}, z_{it}, \varepsilon_{it}),$$

where $y^*_{it} = y_{it} + \bar{x}_{it} \cdot (p^*_{it} - p_{1,it})$. In this equation, p^*_{it} is the household's marginal willingness to pay for the last unit consumed (which may differ from the marginal price, if consumption occurs at the step-point $\bar{x}$ where the price rises from p_1 to p_2). To account for this discontinuous feature when calculating elasticities, we use the following decomposition. Consider an increase in the price of the specific tariff segment in which the household initially consumes. Denoting this initial marginal price as mp, and the consumer's initial marginal willingness to pay as $mwtp$, the total change in consumption can be written as

$$\frac{dx^*}{d(mp)} = \left[\underbrace{\frac{\partial x^*}{\partial(mwtp)}}_{\substack{\text{slope of}\\ \text{demand}}} + \underbrace{\frac{\partial x^*}{\partial y}}_{\substack{\text{marginal}\\ \text{income}\\ \text{effect}}} \cdot \underbrace{\frac{d\,\Delta y}{d(mwtp)}}_{\substack{\text{change in}\\ \text{infra-marginal}\\ \text{expenditure}}} \right] \underbrace{\frac{d(mwtp)}{d(mp)}}_{\substack{0 \text{ if at } \bar{x},\\ 1 \text{ if not}}}$$

where $\Delta y = \bar{x}_{it} \cdot (p^*_{it} - p_{1,it})$ (cf. (3)). The first term in the square brackets is standard. The remaining terms in the bracketed expression yield the (income) effect of changing the infra-marginal price discount. For an optimizing consumer, the term outside the brackets will be zero if consumption occurs at the step-point, $\bar{x}$, and one otherwise.

For the demand specification and two-tier tariff we analyse, this expression takes the simple form:

$$\frac{dx^*_{it}}{d(mp)} = \alpha \cdot \mathbf{1}(x^*_{it} \neq \bar{x}_{it}) + \beta\, \bar{x}_{it} \cdot \mathbf{1}(x^*_{it} > \bar{x}_{it}) \tag{B.1}$$

where $\mathbf{1}(\cdot)$ is the indicator function, and α, β are the price and income coefficients from equation (10). We define a household's monthly price elasticity, η_{it}, in terms of the effect of price on the margin:

$$\eta_{it} = \frac{(mp)_{it}}{x^*_{it}} \cdot \frac{dx^*_{it}}{d(mp)}.$$

A wrinkle arises in computing η_{it}. Since our consumption data are aggregated to an annual level, we do not observe the household's monthly consumption, x^*_{it}, nor its monthly marginal price. Instead, we estimate x^*_{it} with the "plug-in" estimator

$$\hat{x}^*_{it} \equiv E[x^*_{it} \mid w_{it}; \hat{\theta}]$$

using the conditional moment equation derived in (6) evaluated at the estimated parameter values. We then obtain the marginal price estimate, $\widehat{mp}_{it}$, from the household's rate schedule in month t for the quantity $\hat{x}^*_{it}$. Finally, we can compute each household's monthly price elasticity using equation (B.1) as

$$\hat{\eta}_{it} = \frac{\widehat{mp}_{it}}{\hat{x}^*_{it}} \cdot \left[\hat{\alpha}_i \cdot \mathbf{1}(\hat{x}^*_{it} \neq \bar{x}_{it}) + \hat{\beta}_i\, \bar{x}_{it} \cdot \mathbf{1}(\hat{x}^*_{it} > \bar{x}_{it}) \right]$$

where the "hats" indicate estimated quantities.

To obtain the annual price elasticities reported in Tables 3 and 4, we calculate (pointwise) the percentage change in annual electricity consumption for a per cent change in the household's marginal price in *each month* of the year. That is, for each household in the sample we compute

$$\hat{\eta}_i = \frac{1}{x_i} \sum_{t=1}^{12} \hat{\eta}_{it} \cdot \hat{x}^*_{it}$$

where x_i is the household's actual annual electricity consumption. The tables report estimated population means obtained by averaging these household-level annual elasticity estimates using the RECS survey weights.

Income elasticities are obtained similarly, after observing that

$$\frac{dx^*_{it}}{dy} = \beta \cdot \mathbf{1}(x^*_{it} \neq \bar{x}_{it}).$$

Acknowledgements. We thank Jerry Royer of the California Public Utilities Commission for valuable help in accessing and interpreting Commission records, Brent Goldfarb for research assistance, and two anonymous referees for helpful suggestions. White gratefully acknowledges the support of the University of Pennsylvania Research Foundation and the George J. Stigler Center for the Study of the Economy and the State at the University of Chicago.

Pepco Response to OPC Data Request 3-34

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 3

QUESTION NO. 34
Low-Income Households.

a. Please identify the metric or metrics the Company uses to define low-income households in the Company's service area.

b. Please provide the number and percentage of households in your service area that the Company considers low-income for each of the years 2013-2022.

c. Please provide the requested documents in electronic form with all spreadsheet links and formulas intact, source data used, and explain all assumptions and calculations used. To the extent the data requested is not available in the form requested, provide the information in the form that most closely matches what has been requested.

RESPONSE:

a. The Company uses the enrollment in energy assistance programs to classify customers as a low or moderate-income (LMI) customers. Apart from this, the Company is unable to identify LMI customers since the administering program agencies qualify customers, based on income, and then notifies the Company regarding customer eligibility.

b. Based on the number of active customers enrolled in energy assistance programs (see 3.34a) the number and percentage of households considered LMI for 2013-2022 is as follows:

# Unique Households Considered LMI [1]			
Year	# Unique Customers with Active Enrollment LMI [2]	# Residential Customers (December)	% LMI
2013-2016	Data is not available		
2017	26,029	269,947	9.6%
2018	31,327	279,010	11.2%
2019	32,550	285,498	11.4%
2020	28,280	294,511	9.6%
2021	34,130	301,185	11.3%
2022	37,850	310,172	12.2%

[1] Includes Residential Aid Discount (RAD), Low Income Home Energy Assistance Program (LIHEAP) and DC Arrearage Management Program (AMP) enrollments. A customer can be enrolled in one, two or all three programs but will only be counted once in the data provided.

[2] Enrollments vary in length. RAD enrollments are 18 months, LIHEAP enrollments are 12 months and AMP enrollments are 15 months. Enrollments can span multiple years depending on the enrollment start date. Customers are considered LMI as long as the enrollment is active.

Pepco Response to OPC Data Request 3-45

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 3

QUESTION NO. 45
Please describe how the Company collaborates with community organizations and government agencies to address energy affordability issues, and what partnerships have been successful in the past. Provide sources used and explain all assumptions and calculations used.

RESPONSE:

Pepco has long-term relationships with many local community organizations and government agencies who engage with the low-to-moderate-income population who may need energy assistance to promote the Low-Income Home Energy Assistance Program (LIHEAP). The Company's partnership with United Way of the National Capital Area's partnership spans decades. These partnerships provide equitable access to resources to improve the lives of low-income neighbors who may have affordability issues. In addition, the Company has partnerships with other local organizations in the community which include Mary's Center, Interfaith Works, and others.

Locally, Pepco has partnered with the District of Columbia at a plethora of community events to include the weekly summer program called "Beat the Streets" in collaboration with the local Metropolitan Police who canvass the neighborhood providing safety information. During these events, the Company provides energy assistance information. In addition, the Company provides monthly opportunities for customers to enroll in energy assistance during outreach events at apartment complexes, senior facilities, and local food banks. The Company also partners with other utilities by sponsoring energy assistance sign up days.

Please see FC 1176 OPC DR 3-45 Attachment for the number of outreach events held from 2022-2023.

The Company also partners with government agencies to include the Department of Energy and Environment (DOEE) to assist customers with resolving balances on customer's accounts, technical and bill related issues for vulnerable customers, and those needing other extra support. Pepco has increased customer awareness and application intake through effective community outreach and marketing initiatives to raise public awareness of energy assistance programs.
In 2013, the average RAD enrollment was at 17,757 participants. In 2022, participation increased to an average of 25,814 which resulted in a 45% surge in part due to the effective community outreach activities implemented last year (see table below) combined with the expansion of the eligibility requirements.

Pepco Response to OPC Data Request 3-45

Year	Average RAD Enrollment
2013	17,757
2014	16,997
2015	17,513
2016	15,500
2017	17,129
2018	17,947
2019	18,229
2020	17,637
2021	16,904
2022	25,814

IV. MULTIYEAR RATE PLAN

Q10. How does the changing energy policy in the District of Columbia impact the Company?

A10. The Company must make significant long-term investments to meet the policy goals of the District of Columbia and the changing needs of our customers. As the Company evaluates investments to improve reliability and modernize the grid, it is paramount for the Company's investments plans to align with the District of Columbia's policy goals and customer expectations. The current regulatory process in which investments are made and subsequently reviewed in a base rate case does not provide the proper alignment of the Company's investments and performance with the policy goals of the District of Columbia and customer expectations.

Q11. How does the Company's MRP proposal address these concerns?

A11. The Company's MRP proposal, as further explained by Company Witness McGowan and Company Witness Wolverton, is a three-year MRP with forecasted years 2020-2022. The MRP also includes Performance Incentive Mechanisms (PIMs), developed with input from stakeholders, that further drive operational performance and policy objectives. The Company's proposal increases transparency into the Company's future capital investment spending plans and allows stakeholders to evaluate the Company's plans and how these investments align with the District of Columbia's policy goals and customer expectations. The MRP improves the timing of cost recovery by the utility without the need to file annual rate cases. This is important as the Company invests in grid modernization and the infrastructure required to facilitate the

Formal Case No. 1156, Direct Testimony of David M. Velazquez (Exhibit PEPCO (A)), Pages 8-9

District of Columbia's goals of climate action, transportation electrification, and increased resilience.

While many of the investments needed to allow widespread adoption of the technologies discussed above are not in the current capital plan through 2022, we believe it is time to evaluate and adopt an MRP so that parties may start the process of aligning the Company's planned investments with the goals of the District of Columbia and expectations of customers. Adoption of the MRP now will set the framework, so as the Company continues to plan for future investments and evaluates with stakeholders future PIMs around grid modernization, a structure will be well established that facilitates a transparent discussion of investment plans with stakeholders before those investments are made.

The transition from the traditional ratemaking process, which is retrospective, to a prospective MRP will streamline the regulatory process, allow greater transparency into the Company's investments to all stakeholders, reduce the number of rate case proceedings and associated costs, and provide more rate predictability to our customers. The Company is an enthusiastic and essential partner in delivering the District of Columbia and the Commission's goals of addressing climate change. It is timely to move toward a forward-looking mechanism that aligns the Company's investment plans and performance targets with the District of Columbia's policy goals and evolving customer needs. The MRP will allow more timely recovery of the Company's investments and enable the Company to make the investments required to modernize the grid and achieve the District of Columbia and the Commission's progressive energy policy goals.

Exhibit OPC (A)-29
Formal Case No. 1176

Company's Response to the Joint Motion filed on April 20, 2020, Pepco believes this proceeding should move forward. The Company is very much aware of the impact that the pandemic has had on the District of Columbia and the region as a whole and has been working to continue to provide safe and reliable service to our customers throughout this public health emergency. Disregarding all the time and effort expended by the parties and the Commission over this past year is not prudent and would not solve the immediate issues at hand.

In response to Order No. 20349, the Company has crafted the MRP Enhanced Proposal, which incorporates a number of recommendations other parties have made regarding the Original MRP Proposal and on which there is the potential for alignment. Pepco married those recommendations with a number of innovative options to craft the MRP Enhanced Proposal, which results in no overall distribution rate increase until January 1, 2022 for any customer and substantial mitigation of the overall distribution rate increase to customers during 2022. Additional details regarding the MRP Enhanced Proposal are also set forth in the Surrebuttal Testimonies of Company Witnesses Wolverton and Blazunas.

Q19. Are the elements of the MRP Enhanced Proposal severable such that some can be adopted but not others?

A19. No. To be clear, the Company's MRP Enhanced Proposal is an integrated package with interdependent elements designed to operate as a whole in order that this proceeding be resolved expeditiously. The individual elements are not severable as they all need to operate in unison if the MRP Enhanced Proposal is to work. For example, although the Company believes that it has established through the testimonies of Company Witness Hevert that a return on equity of 10.30% is warranted, in order to allow for the customer

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 4

QUESTION NO. 1
Referencing the testimony presented by Witness Cantler at page 5, lines 20-23 and the statement that "[t]he Company's investments during this MYP period are implemented to advance and support various Company objectives such as driving solutions to address climate change, enhancing grid performance, improving social equity and affordability, and looking for new opportunities to enhance customer experience."

a. For each of the identified objectives, explain how the Company intends to measure the Company's performance relative to the stated objective. Provide any objective criteria that the Company proposes to use to measure the success of the MYP period projects in achieving the stated objectives.

b. Provide a breakdown to the MYP projects sorted by the Company objectives that they are intended to advance and support.

c. Provide any cost-benefit analyses performed with respect to the cost of the MYP period projects and the benefits to ratepayers.

RESPONSE:

a. The Company does not have internal metrics in place for measuring the status of the identified objective. The Company's objectives, as noted on pg. 5, lines 17-23 of Company Witness Cantler's Direct Testimony are features of its capital investment strategy throughout this MYP and support a pathway to a Climate Ready Grid. As such, please see the Company's response provided for AOBA DR 1-2. The Company is committed to supporting solutions to address climate change, enhancing our grid's performance, improving social equity and affordability and looking to enhance our customers' experience.

b. The requested breakdown has not been performed. There are too many direct, indirect and tertiary benefits to certain projects to accurately ascertain and/or categorize which singular Company objective a project supports or does not support.

   However, projects, like the implementation of Advanced Distribution Management System, as referenced Pepco (H)-2 on pg. 174, are indicative of enhancing grid performance, and if granted IIJA funding would also, in turn, support affordability for our customer base through subsidization offered by a federal grant. Additionally, there are components of the Company's IT investments referenced in Pepco (H)-2 that will contribute to making energy more affordable by increasing customer participation in

Pepco Response to OPC Data Request 4-1

energy assistance and energy efficiency programs. For a full list of every project and the justification for that project work please refer to Pepco (H)-2 in its entirety.

c. The Company does not generally conduct cost-benefit analysis (CBA), though as mentioned previously, does conduct robust alternative analyses. The Company has conducted cost-benefit analysis in a few areas including: evaluating technologies or initiatives that have not previously been proposed, an initiative that has a societal benefit, or when required by the Commission or regulatory body.

That being stated, and in an effort to be responsive to this request, the Company is currently in the process of compiling relevant information pertinent to CBAs that exist for project work specific to this MYP for a similar request related to AOBA DR 7-25. Once that information has been compiled it will be shared and made available in response.

Pepco Response to OPC Data Request 6-20

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 6

QUESTION NO. 20
Reference Direct Testimony of Cantler at p.22 "The goal of the ADMS Project is to deploy foundational Distributed Energy Resource Management System (DERMS) capabilities - including DER Visualization, DER Estimation, DER Forecasting, and DER Monitoring & Control."

a) Please describe all the functionalities and benefits that will be enabled by the ADMS deployment.
b) Please provide an implementation timeline for when the ADMS and DERMS functionalities will be deployed and available for use.
c) Does the Company intend to procure "digital twin" functionality as part of its ADMS procurement?
d) Where on the system does the Company expect DERMS control functionality to be deployed and how is this determined?

RESPONSE:

a. Please see the Company's Attachment NN that was provided in response to AOBA DR 7-25 for a description of ADMS functionalities and benefits the project will enable.

b. The estimated date that ADMS and DERMS functionalities will be deployed and available for use is 2029.

c. The term "digital twin" is not a term that the ADMS project, or the software vendor is using to describe ADMS capabilities. The term "digital twin" can have various meanings so further clarification would be needed to provide a more specific answer about the functionality in question. However, ADMS does plan to include "Study Mode" models and analysis, as well as unbalanced load flow analysis both of which could be considered "Digital Twin" functionality. ADMS does not plan to include 3D geo-spatial modeling of assets if that is what is implied with "Digital Twin" functionality.

d. Given DERMS is scheduled for a future phase of ADMS implementation, the detailed functionality and capabilities have yet to be fully scoped or defined. As such, an evaluation of where DERMS functionality would reside in the organization has yet to be determined.

SPONSOR: Jaclyn Cantler

Exhibit OPC (A)-32
Formal Case No. 1176

component that can under-collect or over-collect the Company's costs and can make cost recovery unpredictable.

I also noted that in the absence of the BSA, utilities have a strong financial incentive to sell as much electricity or gas as possible. As I explained in my testimony in that case, the BSA is beneficial because it:

- Stabilizes customer bills and improves Pepco's ability to recover its costs;
- Provides Pepco with a more stable stream of revenues and prevents over-collection and under-collection of costs as actual sales vary from test year sales due to weather conditions and/or energy efficiency;
- Eliminates the Company's financial disincentive to promote energy efficiency; and
- Helps ensure fixed-cost recovery.

It is important to note that at the time of the Commission's decision in Formal Case No. 1053, there was uncertainty regarding the impact of revenue decoupling mechanisms, like the BSA, on a utility's overall level of risk. In that proceeding, the Commission held that the Company's authorized return on equity should be reduced in light of the BSA. Since that time, however, as explained by Company Witness Hevert, it has become clear that no such reduction is appropriate.

Q16. Have you changed your position on the BSA?

A16. No, I have not. In fact, as discussed below, I think there are additional reasons to support the BSA beyond those discussed in my prior testimony, including the growth of DER installations.

QUESTION NO. 7

Source of Errata. Please identify with specificity the date that Pepco was first informed or realized that there was a data error that impacted the calculations of the billing determinants for commercial classes with demand charges.

RESPONSE:

For the actual demand billing determinant error corrected in Rebuttal Testimony: Company Witness Blazunas was notified of the potential issue with the demand billing determinants in February 2020 by the Manager of Rate Administration for Atlantic City Electric and Delmarva Power.

For the forecasted demand billing determinant error corrected in the Company's July 28, 2020 Errata and July 30, 2020 Supplemental Testimony: Staff DR 24-24 was received on July 15, 2020. The Company first became aware of the need for the corrections to its forecasted demand billing determinants in review and preparation of the Company's response to Staff DR 24-24.
In preparation of the Company's response to FC 1156 Staff DR 24-24, Company Witness Blazunas determined that the following statement made in his Rebuttal Testimony was incorrect:

> "As discussed later in my testimony, to address this issue, the Company is incorporating updated demand billing determinants into its proposed rate design for the commercial classes with demand rate components for the TTPCF. With respect to the MRP, this issue is avoided as a result of the use of forecasted billing determinants as well as the use of the Company's proposed Annual Billing Determinant Update in the ultimate design of the MRP rates."

The need for the correction is due to the fact that the corrected actual demand (kW) billing determinants should also have been used to calculate corrected load factors with which to derive corrected forecasted demand (kW) billing determinants for each of the three years in the Original MRP Proposal and the MRP Enhanced Proposal.

Formal Case No. 1156, Pepco Response to OPC Data Request 61-3

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1156
RESPONSE TO OPC DATA REQUEST NO. 61

QUESTION NO. 3

Source of Errata. Please confirm that the only source of the data error(s) that impacted the calculations of the billing determinants for commercial classes with demand charges was a report that double counted demand in the months with a rate change.

A. If so confirmed:
   1. Please provide the name and purpose of the report.
   2. When did Pepco start using this report to calculate its billing determinants for commercial classes with demand charges?
   3. Please identify each previous rate cases in which Pepco relied on data from this report.

B. If not so confirmed, please:
   1. Identify in detail each and every source of the data error;
   2. Explain the reason why that source provided incorrect data; and
   3. Provide responses the requests in subsections A.1-3 above.

RESPONSE:

A. The Company confirms that the source of the error is a demand billing determinant report that double counted demand in the months with a "time slice" (such as a month with a rate change). A "time slice" occurs when there are multiple price values within a bill period, and that price is set-up to be prorated within that period.

1. The name of the variant of the Active Billed Report used to provide the actual demand billing determinants for commercial classes with demand rate components in its Application is "Sum of Demand."

2. The "Sum of Demand" variant was in use starting in 2015.

3. Formal Case No. 1150 and Formal Case No. 1139.

QUESTION NO. 6

The implicit under-recovery of rates from the FC 1150 rates going into effect through March 2020 is listed as $20.77 million. What is the projected under-recovery of rates for the period of April 2020 through December 2020? Said another way, what is the projected under-recovery expected to be collected through the BSA due to the use of incorrect demand charges in calculating the FC 1150 rates?

RESPONSE:

The estimated incremental under-recovery for the period April 2020 through December 2020 is $9.57 million ($20.77 million for August 2018 to March 2020 plus $9.57 million for April 2020 to December 2020 equals $30.33 million for the period August 2018 through December 2020). This estimate was obtained using the workpaper provided as FC 1156 AOBA DR 2-10 Attachment and changing the "Current Date" value shown on tab "4. Years Calculation" from 3/31/2020 to 12/31/2020.

RESPONSE TO OPC DATA REQUEST NO. 61

QUESTION NO. 17

Outstanding BSA Balances. Is Pepco proposing to take any financial responsibility over the large outstanding BSA balances? If yes, please explain how Pepco is proposing to do so. If no, please state so.

RESPONSE:

The Bill Stabilization Adjustment (BSA) works as designed in that it allows the Company to collect the difference between its authorized level of revenue and its billed distribution revenue. In every rate case, rates are designed such that they recover the Company's authorized level of revenue. To the extent that billing determinants change, the BSA allows the Company to continue to collect its authorized level of revenue. Assuming that there is not a large disconnect between the billing determinants during the rate-effective period and the billing determinants used to design rates (as happened with the issue surrounding the demand billing determinants), sufficient space under the BSA cap should be created at the time new rates are put in place to unwind deferral balances over time. Nonetheless, the BSA deferral balances appropriately represent amounts approved for collection by the Company but not yet billed. Once new rates are effective, remediation of the billing determinant issue going forward will, all else equal, help to reduce the size of existing deferral balances and the accumulation of future monthly deferrals.

Exhibit OPC (A)-37
Formal Case No. 1176
David E. Dismukes

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 10

QUESTION NO. 6
Please provide all documents and analyses prepared by or on behalf of Pepco discussing or relating in any way to the prudence of its (i) administration of the BSA, (ii) incurrence of the BSA deferral balances relating to the erroneous billing determinants, or (iii) recovery of BSA deferral balances relating to the erroneous billing determinants.

RESPONSE:

As directed in Formal Case No. 1156, Order No. 20755, a series of technical conferences were convened to, among other things, examine the design of the BSA and discuss the impact of the billing determinants error identified in Formal Case No. 1156 on the BSA deferral balance. At the December 9, 2021 BSA Technical Conference, the Company presented the results of its Estimated BSA Drivers Analysis which identified several key drivers of the BSA deferral balance, including the billing determinants error, and estimated the magnitude of revenue under- and over-collections associated with each driver. The Company's December 9, 2021 presentation is provided as FC1176 OPC DR 10-6 Attachment. The results of the Company's analysis are presented on slides 21 through 23 and show that the billing determinant error resulted in an estimated $15.3 million revenue under-collection, approximately $7.4 million of which remained uncollected in the BSA deferral balance as of October 2021.

Order No. 20755 further directed an external audit of the BSA mechanism, including among other things an evaluation of the design of the BSA, a comprehensive evaluation of all Pepco BSA internal controls, and an evaluation of Pepco's BSA Driver Analysis presented at the December 9, 2021 BSA Technical Conference. See FC 1176 OPC DR 5-18 Attachment A for a copy of the final BSA audit report produced by Atrium Economics, the independent auditor selected by the Commission. Specifically, the results of Atrium's BSA deferral drivers analysis are presented in Table 2-11 on page 50 in Atrium Economics final report and estimate that the billing determinant error resulted in approximately $15.1 million in revenue under-collections. As shown in Table 2-16 on page 52, Atrium estimated that as of December 31, 2022, approximately $2.0 million of the Company's BSA deferral balance remained attributable to the billing determinant error, indicating that $13.1 million in under-recoveries related to the billing determinant error had already been reconciled through BSA surcharges.

EXHIBIT LIST

Exhibit OPC (B)-1	Qualifications of Michael P. Gorman
Exhibit OPC (B)-2	Summary of Multi-Year Plan Revenue Requirement Adjustments
Exhibit OPC (B)-3	Summary of Traditional Test Year Revenue Requirement Adjustments
Exhibit OPC (B)-4	Referenced Data Responses

I. INTRODUCTION

Q. PLEASE STATE YOUR FULL NAME, ADDRESS, AND OCCUPATION.

A. My name is Michael P. Gorman. My business address is 16690 Swingley Ridge Road, Suite 140, Chesterfield, MO 63017. I am a consultant in the field of public utility regulation and a Managing Principal of Brubaker & Associates, Inc., energy, economic and regulatory consultants.

Q. HAVE YOU PREPARED AN ATTACHMENT SUMMARIZING YOUR QUALIFICATIONS AND REGULATORY EXPERIENCE?

A. Yes. I have attached Exhibit OPC (B)-1, which is a summary of my regulatory experience and qualifications.

Q. FOR WHOM ARE YOU APPEARING?

A. I am testifying on behalf of the Office of the People's Counsel of the District of Columbia ("OPC" or "Office").

Q. WAS YOUR TESTIMONY PREPARED BY YOU OR UNDER YOUR DIRECT SUPERVISION AND CONTROL?

A. Yes.

II. SCOPE OF TESTIMONY

Q. WHAT IS THE SCOPE AND PURPOSE OF YOUR TESTIMONY IN THIS PROCEEDING?

A. My testimony addresses the Potomac Electric Power Company's ("Pepco" or the "Company") proposed revenue requirements for both its Multi-Year Plan ("MYP") and

Traditional Test Year ("TTY"). I recommend a number of adjustments to the Company's revenue requirements which will be detailed later in my testimony. Finally, I support the revenue requirement impact of adjustments proposed by other OPC witnesses including:

- Christopher C. Walters (Return on Equity)
- Brian C. Andrews (Depreciation)
- Kevin J. Mara (Construction Budget)

Q. DOES THE FACT THAT YOU DID NOT ADDRESS EVERY ISSUE RAISED IN PEPCO'S MYP OR TTY TESTIMONIES MEAN THAT YOU AGREE WITH PEPCO ON THOSE ISSUES?

A. No. The fact that I do not comment on every specific issue raised by Pepco should not be construed as an endorsement of, agreement with, or, acquiescence to the Company's position on such issues. Likewise, OPC Witness Dismukes sponsors testimony recommending rejection of the MYP. The fact that I sponsor testimony on the revenue requirements for the duration of the MYP should not be construed as being contrary to Dr. Dismukes' recommendation. Instead, I am addressing the MYP revenue requirements in the event the Public Service Commission ("Commission") does not accept Dr. Dismukes' recommendation.

III. <u>SUMMARY OF TESTIMONY</u>

Q. PLEASE SUMMARIZE YOUR TESTIMONY AS IT PERTAINS TO PEPCO'S OVERALL REVENUE REQUIREMENTS FOR BOTH ITS MYP AND TTY.

A. In my testimony, I will summarize adjustments to Pepco's claimed revenue requirements offered by witnesses sponsored by OPC for both the MYP and the traditional revenue requirement.

MYP Revenue Requirement Adjustments.

As shown in Table 1, based on revenue requirement adjustments sponsored by the OPC in this case, Pepco's MYP revenue deficiency is overstated by $56.4 million in 2024, $63.9 million in 2025, and $71.7 million in 2026 (Table 1).

TABLE 1

Multi-Year Plan
Revenue Requirement Adjustments
($ Millions)

Line	Description	MYP Year 1 12ME Dec 2024 (1)	MYP Year 2 12ME Dec 2025 (2)	MYP Year 3 12ME Dec 2026 (3)
1	Claimed Revenue Deficiency	$ 116.4	$ 153.4	$ 190.7
	Adjustments:			
2	Return on Equity	$ 25.0	$ 26.8	$ 28.3
3	Depreciation	25.2	24.6	23.7
4	MYP Capital Projects	1.9	5.5	9.8
5	Sales Forecast	0.7	2.1	4.3
6	Service Company Cost Escalation	1.6	2.8	3.7
7	Deficient Deferred Income Taxes	1.5	1.4	1.4
8	Regulatory Asset Amortization	0.6	0.6	0.7
9	Total Adjustments	$ 56.4	$ 63.9	$ 71.7
10	Adjusted Revenue Deficiency	$ 60.1	$ 89.5	$ 119.0

Traditional Year Revenue Requirements Adjustments

Similarly, Pepco's TTY revenue deficiency is also overstated by $60.4 million (Table 2).

TABLE 2

Traditional Test Year
Revenue Requirement Adjustments
($ Millions)

Line	Description	12ME Dec 2023 (1)
1	Claimed Revenue Deficiency	$ 108.2
	Adjustments:	
2	Return on Equity	$ 20.0
3	Depreciation	23.4
4	TTY Capital Projects	3.2
5	Annualized Revenues	1.1
6	Deficient Deferred Income Taxes	1.5
7	Regulatory Asset Amortization	0.5
8	Inflation	0.4
9	BSA Deferral	10.3
10	Total Adjustments	$ 60.4
11	Adjusted Revenue Deficiency	$ 47.8

The rate of return adjustment in the tables above is supported by my colleague, Mr. Christopher C. Walters. Mr. Walters demonstrates the unreasonableness of Pepco's recommended 10.5% return on equity ("ROE"). Adjusting the ROE to a reasonable level—i.e., to 9.30% from 10.5%--reduces Pepco's revenue requirements during the MYP by the amounts shown above. Adjusting the ROE to 9.55% from 10.5% to reflect different risk associated with a TTY as opposed to an MYP reduces Pepco's TTY revenue requirement by the amount shown above. My adjustment to reflect Mr. Walters' ROE is included as part of my Exhibit OPC (B)-2 (MYP) and Exhibit OPC (B)-3 (TTY) which are summaries of my revenue requirement adjustments.

The depreciation adjustment in the tables above is supported by my colleague, Mr. Brian C. Andrews. Mr. Andrews supports OPC's proposed depreciation rates. The tables above include the test year depreciation expense adjustments reflecting the test year plant balances and Mr. Andrews' proposed depreciation rates.

OPC witness Kevin J. Mara, Exhibit OPC (E), recommends several adjustments to the construction and capital investment costs included in Pepco's MYP. Mr. Mara recommends a number of projects be canceled or delayed due to a reduction in load, he takes issue with the allocation of sub-transmission costs to the District, and he recommends some costs be disallowed due to changes in the Downtown Resupply Project. Mr. Mara also recommends several projects be removed from the TTY because they may not be completed and provide benefits to ratepayers during the rate-effective period. I have included the revenue requirement impact of Mr. Mara's adjustments on my summary exhibits.

Q. PLEASE SUMMARIZE WHY THERE IS BOTH A MYP AND A TTY IN THIS PROCEEDING.

A. On April 13, 2023, Pepco filed its application to implement a second MYP for 2024 to 2026. The MYP proposed revenue requirement increases of $116.4 million in 2024, $36.9 million in 2025, and $37.3 million in 2026. These revenue requirements are shown on the Company's Exhibit PEPCO (B)-1. Ms. O'Donnell in her April 2023 direct testimony argues Pepco is seeking approval of a "Climate Ready Pathway that provides the Commission, customers and stakeholders with a forward-looking plan and a detailed view of the investments the Company intends to make from 2024 through 2026."[1] Pepco's MYP application also included investments from 2023 that were placed in service but were not yet reflected in rates due to the "stay-out provision" approved in Formal Case No. 1156 ("FC 1156").

On July 28, 2023 in Order No. 21886 the Commission directed Pepco to make two additional filings in response to comments filed by OPC, the Apartment and Office Building Association of Metropolitan Washington ("AOBA"), and the District of Columbia Government ("DCG"). The Commission directed Pepco to file supplemental direct testimony that 1) addressed the benefits of, problems identified, and lessons learned from the MYP pilot the Commission approved in FC 1156 and 2) supported a traditional one-year rate case for a calendar year 2023 test year. Pepco filed its supplemental testimony regarding the first MYP on August 31, 2023 and its supplemental testimony with the TTY on October 16, 2023.

Pepco's TTY is based on a calendar year 2023 test year and includes six months of actual data (January 2023 to July 2023) and six months of forecasted data (July 2023 to December 2023). The TTY supports a $108.2 million revenue requirement. This revenue requirement is shown on the Company's Exhibit PEPCO (2B)-1.

---

[1] Exhibit PEPCO (A), O'Donnell Direct at 5.

Q. HOW WILL THE REMAINDER OF YOUR TESTIMONY BE ORGANIZED?

A. In Section IV, I will discuss my recommended revenue requirement adjustments to Pepco's MYP. In Section V, I will discuss my recommended revenue requirement adjustments to Pepco's TTY. Several of my revenue requirement adjustments are applicable to both the MYP and TTY. For those adjustments I will use the MYP section to discuss my reasoning rather than duplicate my testimony in both the MYP and TTY sections. In Section VI, I will respond to Pepco's proposal to earn a return on its Bill Stabilization Adjustment ("BSA") deferral balance in the TTY. I note that OPC Witness Dismukes also sponsors testimony addressing the BSA.

IV. <u>MULTI-YEAR PLAN REVENUE REQUIREMENT ADJUSTMENTS</u>

Q. PLEASE BRIEFLY SUMMARIZE YOUR PROPOSED ADJUSTMENTS TO PEPCO'S MYP REVENUE REQUIREMENTS?

A. I recommend several adjustments to Pepco's MYP revenue requirements, as shown above in Table 1.

- Pepco's sales forecast is understated because it is based on unbalanced projections for expected use per residential customer. The sales projections at current rates needed to be adjusted to reflect symmetrical and balanced outlooks of changes in use per customer.

  Specifically, Pepco's residential sales forecast reflects the Company's energy efficiency forecast, which will lower sales during the forecast period, but does not reflect residential load growth from increased electrification. Pepco's cost of service projections do include projected capital expenditures needed to accommodate expected electrification conversion during the forecast period. This imbalance in assumptions made to produce the projected cost of service in the MYP is unreasonable and should be corrected. I recommend the residential sales forecast be based on the Company's 2023 use per customer forecast rather than the Company's MYP forecast which assumes electricity use per residential customer will decrease each year during the forecast period. A flat projection of use per customer accommodates the outlook of both reduction in use per customer due to conservation, and the increase in use per customer for electrification. These are important factual matters the Commission should resolve in setting Pepco's cost of service.

- Pepco's O&M forecasting process diverges from the Commission-approved methodology used in the previous MYP and as a result offers less transparency into the cost drivers of Pepco's distribution operations in the DC jurisdiction. Pepco forecasts its O&M will escalate during the MYP based on a projection of total company and affiliate service company costs, and a projection of the jurisdictional allocation of these costs to the DC jurisdiction. In the last MYP, O&M expenses were projected using the Company's actual O&M costs and then applying an inflation escalator.

  A primary contributor to the 2023 O&M escalation is an increase in the affiliate service company charges which are allocated to Pepco's DC jurisdiction. Also, total distribution allocated labor costs increased by 39% in 2023 relative to 2022. This material cost escalation has not been fully explained or justified. I recommend these projected costs escalations be reduced to a reasonable level based on jurisdiction historical costs to Pepco's actual cost forecasted 2023 level for the MYP. At a minimum, the bases for and reasonableness of Pepco's proposals are material issues of fact that the Commission must resolve.

- Pepco is requesting authority to recover its deficient deferred income taxes just as it did in its previous proceeding, FC 1156. In this previous proceeding, the Commission denied Pepco's request to recover these deferred costs from jurisdictional customers. Pepco has not offered new evidence in support of the recovery of these deferred costs. Therefore, I recommend that the Commission again deny recovery of these deferred costs for setting prospective rates.

- Pepco is requesting to recover several of its regulatory assets, including deferred COVID-19 costs, over five years. I recommend Pepco recover these costs over six years, or approximately two rate case cycles, as a more balanced and fair recovery period. Failure to align the recovery period with an expected rate cycle period will allow Pepco to over recover these regulatory assets costs.

A. MYP Sales Forecast

Q. PLEASE PROVIDE AN OVERVIEW OF HOW PEPCO FORECASTS ITS REVENUES DURING THE MYP PERIOD.

A. Pepco provides a forecast of its billing determinants during the MYP as Exhibit PEPCO (K), Ekaterina (Kate) Efimova's direct testimony and exhibits. The billing determinants forecast includes estimates for Pepco's number of customers, the amount of kWh sales, and kW demand during the MYP period. The forecasted billing determinants are then applied to Pepco's present and proposed rates for the various rate classes to calculate the MYP revenues. Ms. Efimova sponsors Pepco's billing determinants forecast and she writes regarding the forecast:

> The goal of billing determinants forecasting is to produce a reasonable outlook incorporating all of the most relevant information available to a forecaster. The forecast of billing determinants is specifically based on historical data collected from customer bills or meters, i.e., billed sales (kWh), customers (count of contracts), and billed demand (kW). Additional information about major factors impacting billing determinants, such as weather and economics, is typically used to explain historical trends. Forecasted future changes in these major factors are then used to forecast billing determinants.[2]

Ms. Efimova lists the number of households and overall economic activity as the most important drivers for the number of customers forecast. She lists weather, economic activity, and energy efficiency/demand side management programs as the most important drivers for the energy sales forecast. Finally, she states the billed demand forecast is closely related to and has the same drivers as the energy sales forecast.

[2] Exhibit PEPCO (K), Efimova Direct at 4.

Pepco uses an econometric regression analysis to determine the relationship between the drivers above and Pepco's historical billing determinants. Exhibit PEPCO (K)-1 provides more details on the Company's forecast and forecasting process. The results of the forecast are provided in the subsequent (K) exhibits. Pepco relies on historical data up through September 2022 in its analysis. Ms. Efimova outlines the overall trends in the forecast drivers on pages 20-21 of her direct testimony.

Q. WHAT ARE THE RESULTS OF PEPCO'S FORECAST?

A. Ms. Efimova estimates that Pepco's electric sales will decline by 1.3% per year over the MYP period. She writes regarding forecasted sales for each rate class:

> Residential class sales will grow 0.1% which is slower than the 1.2% pre-COVID-19 growth due to slower economic growth and growing impacts of EE. Small Commercial class sales will decline (2.5%) which is lower than the (1.8%) pre-COVID-19 growth due to stronger EE. Large Commercial class sales will decline (1.8%) annually over the MYP period after declining (1.1%) during the pre-COVID-19 period of 2017-2019 due to growing impacts of EE.[3]

"EE" in the quote above refers to energy efficiency. EE is driving the decrease in sales per customer in the Company's forecast. Ms. Efimova writes regarding customer growth:

> Pepco's total electric customers are expected to grow by 1.6% per year over the MYP period, driven by Residential class growth of 1.8%. The Residential MYP growth is slower than pre-COVID-19 period due to slower economic growth. The Small Commercial customers are expected to decline (0.3%) driven by slower expected economic growth. The Large Commercial customers will grow 0.5% per year over the MYP period which is slower than pre-COVID-19 growth driven by economic weakness and the continuing impact of COVID-19.[4]

---

[3] Exhibit PEPCO (K), Efimova Direct at 21.

[4] Exhibit PEPCO (K), Efimova Direct at 22-23.

Ms. Efimova concludes by arguing Pepco's forecast is reasonable.[5]

Q. DO YOU HAVE ANY CONCERNS WITH PEPCO'S MYP REVENUES FORECAST?

A. Yes. I recommend that the Commission find that the Company's projected energy use per customer over the forecast period understates a reasonable estimate of residential sales at current rates throughout the MYP period. Understating electricity use per customer results in less forecasted sales and, therefore, underestimates revenues at present rates and overstates the claimed revenue deficiency.

My primary concern with Pepco's forecast is that the Company includes factors that decrease use per customer sales, such as energy efficiency, but excludes factors that may increase use per customer, such as conversion to electrification in the forecasted period. Ms. Efimova acknowledges the Company's sales forecast assumptions did not include an offset to conservation sales impacts at pages 15-16 of her direct testimony.

> The Company did not make an explicit assumption regarding building electrification impacts on the billing determinants forecast. However, changes in appliance and building standards used by customers are implicitly captured through the historical sales data that runs through the models. Existing trends in appliances and building standards will thus drive similar impacts in the MYP forecast. No additional assumptions regarding future standards or potential changes to related policies are assumed in the forecast.[6]

I am concerned that Pepco's assumptions are underestimating sales in the MYP period.

5 Exhibit PEPCO (K), Efimova Direct at 25-26.

6 Exhibit PEPCO (K), Efimova Direct at 15-16.

Q. DID YOU REVIEW PEPCO'S ENERGY EFFICIENCY FORECAST?

A. Yes. Pepco includes its energy efficiency forecast as Exhibit PEPCO (K)-6. Ms. Efimova's Exhibit PEPCO (K)-1 discusses the impact of energy efficiency on the forecast.

> The EE data are entered into the residential average use sales model on a per customer basis by dividing the Residential EE forecast by the residential customers. The cumulative monthly EE data are directly entered into other Residential and Commercial econometric sales models as an independent variable. Please see Attachment 'Pepco DC (K)-6.xlsx' for the underlying EE data and the calculations used to get the data into a monthly cumulative series used in the sales models. The MMA model uses Residential EE and the GSLV and MGTLV & GTLV use Commercial EE. EE is expected to reduce Company sales; in the models the sign of the coefficient is expected to be negative. EE is one of the largest impacts that decreases sales.[7]

The Company, however, acknowledges that the results of the EE programs to reduce sales is uncertain and in some cases untested. Exhibit PEPCO (K)-6 includes forecasted energy savings for energy efficiency programs that have not yet been evaluated or commenced. Pepco provided more detail on PEPCO (K)-6 in discovery:

> **QUESTION NO. 39c:** Please provide the most recent program evaluation for each of the programs listed in PEPCO (K)-6.
>
> **RESPONSE:** Evaluations for the Company run programs listed in Pepco (K)-6 are not available as Pepco administered programs through FC1160 have yet to be approved and commence. For DC Sustainable Energy Utility please refer to the DCSEU for any evaluations done on their behalf.
>
> **QUESTION NO. 39d:** Please describe the Company's process for forecasting the energy efficiency savings for programs that do not show any actual savings (or savings before 2023).
>
> **RESPONSE:** Savings forecasts for energy efficiency programs that had no actual savings prior 2023 were based off the forecasted savings that were presented in Pepco's FC1160 filing. The Company only included savings

[7] Exhibit PEPCO (K)-1 at 27.

> from programs that were initially approved with modifications by the Commission in Order 21417.
>
> **QUESTION NO. 39e:** Please describe the Company's process for forecasting the energy efficiency savings for the behavior based program
>
> **RESPONSE:** The Company's forecast for the behavior-based program was taken from its FC1160 filing. The FC1160 forecast was derived from previously evaluated savings of the behavior-based programs the Company administers in nearby Maryland jurisdictions rescaled to the District's population.[8]

Q. DID YOU REVIEW PEPCO'S ELECTRIFICATION ASSUMPTIONS?

A. Yes. As mentioned above, Ms. Efimova states the Company's forecast did not include an assumption regarding electrification in forming its sales forecast over the MYP. This was confirmed in discovery in response to AOBA Data Request 1-11.

> Currently, the Company does not directly include electrification into its 10-year capacity/load forecasts. While identified and specific near-term usage and planned capacity additions have been incorporated, electrification has not been projected.[9]

Despite excluding the increase to sales due to electrification in its MYP projections, Pepco did include costs in the MYP period associated with its outlook for electrification initiatives. Pepco Witness Ms. O'Donnell argues on page 5 of her direct testimony that, "more interactive grid is necessary to accommodate increasing deployment of distributed energy resources and manage increased electrification load."[10] She continues, "Pepco's Climate Ready Grid investments create a platform to support the proliferation of beneficial

---

8 Pepco's response to Data Request OPC 13-39, provided in Exhibit OPC (B)-4.

9 Pepco's response to Data Request AOBA 1-11, provided in Exhibit OPC (B)-4.

10 Exhibit PEPCO (A), O'Donnell Direct at 5.

electrification measures in the District's transportation, buildings, and commercial sectors."[11]

Pepco was asked about this statement and its relationship to Pepco's load forecast in discovery in DCG Data Request 1-4.

> **QUESTION NO. 4 -** Refer to Pepco Response to AOBA Data Request No. 11-1(a). If Pepco does not directly include electrification into its 10-year capacity/load forecasts, explain why "proposed investments in this MYP are fundamental to preparing the grid for customer adoption of electrification in the near-term" as stated in the Direct Testimony of Witness O'Donnell at page 10.
>
> **RESPONSE -** The Company assumes that the question meant to reference Pepco's response to AOBA 1-11(a). The Company does not forecast electrification separately from other load, at this time, as noted in the response to 1-11(a). However, the Company does incorporate near term usage when available.
>
> The proposed investments in this MYP are fundamental to preparing the distribution system because the distribution system needs to operate efficiently and effectively, especially with the growth in electrification that will be required to advance the District's decarbonization and clean energy goals. As noted in Witness O'Donnell's testimony (page 10, line 17-20) as customers increase their use of electricity at homes and businesses across the District, it will be even more vital that the grid function smoothly and provide consistent, reliable service.[12]

The evidence demonstrates that Pepco's MYP test year forecast is imbalanced because Pepco includes the costs related to electrification but ignores the increased sales that will be produced by electrification.

---

11 Exhibit PEPCO (A), O'Donnell Direct at 5.

12 Pepco's response to Data Request DCG 1-4, provided in Exhibit OPC (B)-4.

Q. DOES PEPCO EXPECT AN INCREASE IN SALES DUE TO THE CONVERSION TO ELECTRIFICATION?

A. Yes. Pepco witness Jaclyn Cantler supports the Company's distribution capital investments being made in the MYP. She also supports Exhibit PEPCO (H)-1, which includes the Company's peak load forecast. Ms. Cantler's direct testimony states that Pepco is preparing for increased load from electrification.

> **Q11. How does the Company's capital investment strategy support the Climate Ready Grid discussed in Company Witness O'Donnell's Direct Testimony?**
>
> A11. The Climate Ready Grid is a series of investments into, among other things, the reliability and resiliency of Pepco's distribution system in the face of the energy transformation. This transformation has been established in District policy and requires a significant shift to electrification. Pepco's climate ready grid addresses the operational readiness to reliably accommodate these shifts and prepare the system for current and future climate impacts. The construction report, which I will discuss later in my testimony, contains investments that are needed to support reliability and resiliency which is increasingly important as customers rely on electrification for their everyday needs – including transportation, heating and cooling.[13]

Despite the capital expenditures included to address electrification, Pepco's load forecast included as Exhibit PEPCO (H)-1 states, "the forecasted loads do not include prospective electrification projects driven by legislative actions that have not been finalized."[14]

---

[13] Exhibit PEPCO (H) Cantler Direct at 6.

[14] Exhibit PEPCO (H)-1 at 21.

Q. DOES PEPCO'S LOAD FORECAST RESULT IN A DECREASE TO RESIDENTIAL USE PER CUSTOMER SALES OVER THE FORECAST PERIOD?

A. Yes. Pepco assumes an energy use per residential customer of 625 kWh per month in 2024. Pepco assumes this will decrease to 615 kWh in 2025 and to 605 kWh in 2026. This projection is well below the five-year average weather normalized use per customer of 646 kWh per month as shown below. Table 3 is supported by my Exhibit OPC (B)-5.

TABLE 3

Weather Normalized Use Per Customer

Line	Description	Monthly Avg. kWh Use per Customer (1)	Percent Change (2)
1	2018	666	
2	2019	654	-1.9%
3	2020	651	-0.4%
4	2021	642	-1.4%
5	2022	618	-3.9%
6	5-Year Avg.	646	-1.9%
	Forecast		
7	2023	636	
8	2024	625	-1.6%
9	2025	615	-1.6%
10	2026	605	-1.7%

Sources:
Exhibit OPC (B)-5.

Pepco has not proven that its use per customer assumptions are reasonable and reflect all potential drivers of electricity use in the district during the MYP period.

Q. ARE YOU PROPOSING AN ADJUSTMENT TO PEPCO'S SALES FORECAST?

A. Yes. I recommend the Commission base the MYP sales forecast on Pepco's normalized use per customer for 2023, or a 636 kWh per month per residential customer. Changes in the actual use per customer during the MYP period will be based on, among other drivers, energy efficiency and electrification impacts on households' electric use. Pepco has not provided evidence or analysis that reliably indicates if a use per customer projection based on a balanced forecast will result in an increase, decrease or similar level of electricity sales. Assuming no change in use per customer is the most conservative assumption for the MYP period.

To the extent Pepco's sales forecast used to set rates differs from actual sales while the rates are in effect, the Company has the protection of the MYP reconciliation process to ensure it recovers its cost of service. Consequently, my proposal is more reasonable and balanced than Pepco's projection.

Q. CAN YOU BRIEFLY DESCRIBE THE MYP'S PROPOSED ANNUAL RECONCILIATION PROCESS?

A. Pepco Witness Leming discusses the MYP's annual reconciliation process. The process includes an Annual Informational Filing that compares projected data to actual data, a consolidated reconciliation and prudency review in a subsequent rate case, and a final reconciliation and prudency review after the conclusion of the MYP. Mr. Leming states this comparison aligns with the process the Commission previously approved for the MYP pilot in Formal Case No. 1156. The annual information filing will be submitted by Pepco within 90 days of the end of 2024 and 2025. Mr. Leming writes regarding the annual information filing:

> If the Company is over-earning, parties to the proceeding could petition (or the Commission on its own accord could initiate) for a review of whether rates should be decreased if a significant disparity between revenues and expenses to the detriment of customers is demonstrated. If the Company is under-earning, it will not have an opportunity for rates to be increased as a part of the annual informational filing. This process is meant to serve as an information review with any rate adjustment to occur within a reconciliation and prudency review, such that the MYP does not result in individual reconciliations and rate updates each year, absent a significant disparity between revenues and expenses.[15]

While the MYP process aims to avoid annual reconciliations, the MYP process does allow a party, including Pepco, to petition the Commission to reopen the MYP.

Q. WHAT IS THE IMPACT OF YOUR ADJUSTMENT TO RESIDENTIAL SALES ON THE MYP REVENUE DEFICIENCY?

A. My adjustment is included as Exhibit OPC (B)-6. As shown on my exhibit, forecasting Pepco's revenues at present rates using a more reasonable use per customer assumption lowers the Company's claimed revenue deficiency by $678,429 in 2024, $2,077,428 in 2025, and $4,299,154 in 2026.

My exhibit uses the same forecasting process as Pepco. I used the same number of customers forecast, electric vehicles forecast, and solar forecast as Pepco. Once Pepco calculated a monthly use per customer using its regression analysis, the Company then applied a small adjustment for electric vehicles and solar adoption. Pepco then multiples this adjusted monthly use per customer by its forecasted number of customers to calculate

---

[15] Exhibit PEPCO (B), Robert Leming Direct at 14.

its kWh sales forecast. The forecasted sales then flow into the PEPCO (E) exhibits which calculates the MYP revenues at present rates. My exhibit only changes the use per customer assumption and does not adjust Pepco's number of customers forecast or other assumptions.

B. MYP Cost Escalation

Q. PLEASE DESCRIBE HOW PEPCO FORECASTED ITS OPERATION AND MAINTENANCE ("O&M") EXPENSE FOR THE MYP PERIOD.

A. Pepco's MYP forecasts the expected O&M (and capital investments) for the three-year period using the Long Range Plan ("LRP") developed by Pepco Holdings LLC ("PHI"). Pepco's application also outlines the 2022 historical test year and 2023 bridge year. Exhibit PEPCO (B)-1 is a summary of the historical test year, 2023 bridge year, and MYP period revenue requirements. The Commission requires the Company to identify baseline revenues and cost information and to explain how the Company forecasts its cost of service as part of its alternate forms of regulation ("AFOR").[16]

Table 4, below, highlights the Company's forecasted O&M expense from 2023 to 2026. While Pepco limited its projected escalation of O&M expense during the MYP to 1.93%,[17] its projected O&M escalation was 9.2% in the 2023 bridge year over the 2022

[16] Exhibit PEPCO (B), Leming Direct at 27.

[17] Exhibit PEPCO (A), O'Donnell Direct at 32.

historical year. The overall O&M annual growth rate included in the MYP forecast (2022 to 2026) is 3.7%.[18]

TABLE 4

Pepco's MYP O&M Expense Forecast
($000)

Line	Year	O&M Expense (1)	Percent Increase (2)
1	2022 HTY	$ 164,178	
2	2023 Bridge	179,338	9.23%
3	2024 MYP	185,235	3.29%
4	2025 MYP	186,125	0.48%
5	2026 MYP	189,910	2.03%
6	5-Year Annual Growth Rate		3.71%
7	MYP Annual Growth Rate		1.93%

Source:
Exhibit PEPCO (B)-1.

As explained above, the MYP O&M forecasts were developed within the PHI LRP process. The following Company witnesses sponsored certain components of these O&M cost projections:

- Phillip S. Barnett forecasts O&M at Pepco and the PHI Service Company ("PHISCO") for non-operational departments
- Phillip Vavala forecasts O&M for Operations
- Morlon D. Bell-Izzard forecasts O&M for Customer Operations

18 Exhibit PEPCO (B), Leming Direct at 5-6.

Pepco witnesses Barnett, Vavala, and Bell-Izzard describe PHI's LRP noting that O&M budgets are completed at a "Management View" and include total Pepco direct O&M and total PHISCO O&M before an allocation is made to the Pepco DC jurisdiction. Hence, the forecast process includes affiliate and Pepco jurisdictional combined cost flowed by an allocation of combined costs to respective jurisdictions. Mr. Barnett presents the Pepco Adjusted O&M costs on a Consolidated Pepco Reporting Basis which includes Pepco's allocation of total PHISCO affiliate service company costs. Witness Leming discusses how these O&M costs are allocated to the Pepco DC distribution jurisdiction.

Mr. Leming presents Pepco's O&M costs in his Table 6 which I have replicated below as my Table 5. Mr. Leming provided his jurisdictional cost of service study as Exhibit PEPCO (B)-3.

TABLE 5

Allocation of Pepco's MYP O&M Expense Forecast
($000)

Line	Description	HTY 2022 (1)	Bridge Year 2023 (2)	MYP Year 1 2024 (3)	MYP Year 2 2025 (4)	MYP Year 3 2026 (5)
1	O&M - Management View	$ 635,974	$ 663,036	$ 684,897	$ 700,145	$ 717,738
2	Less: Non-Pepco PHISCO Allocated Costs	(146,687)	(163,006)	(172,960)	(180,379)	(184,217)
3	O&M - Consolidated Pepco Reporting	$ 489,287	$ 500,030	$ 511,937	$ 519,766	$ 533,521

Source:
Leming Direct Testimony at 39.

Q. IS PEPCO USING A DIFFERENT METHODOLOGY FOR ITS O&M FORECAST THAN WHAT WAS APPROVED IN FC 1156?

A. Yes. In FC 1156, Pepco submitted two MYP proposals. The first used the Company's LRP to forecast revenues and expenses and the second was based on a historic period with annual additions to plant in-service and O&M expense tied to an escalation factor. The Commission accepted Pepco's second proposal with modifications, which is referred to as the Modified Enhanced Multiyear Rate Plan ("Modified EMRP") pilot. The modifications included a reduced return on equity (9.275% instead of 9.70%) and a reduction in the inflation escalator, among other modifications. The Commission used an inflation escalator of 2.17% instead of Pepco's proposed 2.5%. The Commission concluded:

> Specifically, the Modified EMRP uses an escalation factor independent from actual cost changes. The escalator incentivizes Pepco to control costs over the course of the EMRP and benefits ratepayers since Pepco is prevented from escalated costs in a manner that equals its desired revenue requirements.[19]

Mr. Leming states the Company developed the O&M expenses in this application based on PHI's LRP (rather than the index approached used in the Modified EMRP pilot), and he believes this methodology is more reasonable and appropriate. He states:

> Leveraging the Company's LRP for the projection of revenues and expenses provides all parties in the case and customers with transparency into the Company's plans and ensures that there is a basis for the revenue requirements rooted in plans that support the District's goals and policies, while ensuring that customers continue to receive reliable service.[20]

* * *

[19] FC1156 Order and Opinion No. 20755, June 8, 2021, page 63.

[20] Exhibit PEPCO (B), Leming Direct at 9.

> The LRP reflects the Company's best current estimates regarding the specific distribution programs and initiatives Pepco will undertake in the District and considers impacts of inflation and supply chain issues during the 3-year term of the MYP.[21]

Table 3 of his direct testimony compares the Company's proposed MYP in this case with the Modified EMRP pilot. His table shows that the proposed approach for forecasting O&M costs in the second MYP is the forecast from the Long Range Plans while the Modified EMRP pilot used an index.

Ms. O'Donnell explains in her direct testimony why the Company did not use an escalation factor similar to the Modified EMRP pilot. She argues that the LRP is forward-looking and reflects cost projections that take into account the specific distribution programs and initiatives Pepco intends to implement. Ms. O'Donnell also argues that the LRP reflects the Company's best current estimates regarding inflation and supply chain issues that may be experienced during the MYP period. Ms. O'Donnell also argues the reconciliation process ensures customers eventually pay for the actual cost of service.

Pepco further explained its decision to not use an index or escalator approach for this MYP in response to DCG Data Request 4-3.

> **QUESTION NO. 4-3**
>
> C. Explain how the LRP approach improves the Company's incentive to achieve cost-efficiencies compared to the index approach.
>
> **RESPONSE**
>
> C. The LRP approach improves the Company's incentive to achieve cost efficiencies by aligning the baseline from which to seek efficiencies to the

[21] Exhibit PEPCO, Leming Direct at 9.

> work it expects to perform, rather than a general inflation factor which may or may not correlate with the planned work in a given year.[22]

Q. DID PEPCO SUMMARIZE THE PRIMARY DRIVERS OF ITS FORECASTED O&M COST PROJECTIONS?

A. Yes. Witness Barnett states the primary drivers of the O&M cost increase in his areas are merit increases, higher pension and Other Post-Employment Benefits ("OPEB") costs, and higher Business Services Company ("BSC") and Information Technology ("IT") costs.[23] Witness Vavala states the primary drivers of the O&M cost increase in his areas are merit increases, higher pension and OPEB costs, contracting costs, technical services, and transmission and substation (distribution) costs.[24] Witness Bell-Izzard states the primary drivers of the O&M cost increase in his areas is payroll / merit increases.[25]

Q. DOES THE COMPANY'S REVISED METHOD OF FORECASTING ITS MYP O&M EXPENSE PROVIDE SUFFICIENT TRANSPARENCY TO ENSURE THAT CUSTOMERS' INTERESTS ARE PROTECTED?

A. No. The Company's updated method of forecasting O&M expense under an MYP is largely tied to consolidated Company operations, including service company fees rather than tracking estimates for jurisdictional Pepco operating expenses, and explaining changes to these costs based on expected inflationary escalation factors, weights changes

---

22 Pepco's response to Data Request DCG 4-3, provided in Exhibit OPC (B)-4.

23 Exhibit PEPCO (G), Barnett Direct at 17.

24 Exhibit PEPCO (I), Vavala Direct at 6-7.

25 Exhibit PEPCO (J), Bell-Izzard Direct at 36-37.

or other methods that can be used to gauge the reasonableness of projected prospective changes relative to historical actual costs in forecasting cost of service in an MYP. Customers should be protected by maintaining as much transparency as possible in forecasting cost of service in the MYP. The Commission achieved this objection when it previously approved method of forecasting O&M expenses regarding the Modified EMRP pilot. Pepco has not identified any deficiency with the Commission's prior approach or provided evidence to support factual determination that its proposal is superior to the prior approach. I believe the new approach is less transparent and reduces customer rate setting protections relative to the prior approach. .

Q. PLEASE EXPLAIN WHY THE NEW LRP APPROACH OF BUDGETING O&M EXPENSE IS LESS TRANSPARENT THAN THE BUDGETING PRIOR APPROACH PREVIOUSLY APPROVED BY THE COMMISSION?

A. As noted above, Ms. O'Donnell argues in her direct testimony that the MYP reflects the Company's best current estimates regarding inflation and supply chain issues. Mr. Leming makes the same argument in his direct testimony. Importantly, however, Pepco does not detail its inflation outlook during the MYP in its new approach of forecasting O&M. Witness Barnett describes the LRP process in his direct testimony:

> PHI's operational plans are updated annually for current operating conditions and safety and reliability goals and the PHI LRP process begins with a kick-off meeting that is led by Finance to provide key instructions to the responsibility areas on the timing of deliverables, key planning assumptions, and guidance on responsibilities for milestones in the development of the LRP. Responsibilities areas are provided with targets and O&M planning assumptions including such things as inflation, merit increases, fringe benefits and pension/OPEB. Any significant changes in

> operational goals and regulatory requirements are taken into consideration in the LRP process.[26]

LRPs for the three O&M areas were provided as Exhibits PEPCO (G)-1 and (G)-2 (non-operations functions), PEPCO (I)-1 and (I)-2 (operations), and PEPCO (J)-1 and (J)-2 (customer service). Nothing in Pepco's testimony or the plans themselves provides the Company's O&M planning assumptions, e.g., an inflation estimate for the MYP. Instead, Pepco cites the average Consumer Price Indices for 2021 and 2022 of 6.7% as evidence that purportedly shows its O&M cost increases during the MYP are reasonable.[27] Pepco also describes 6.7% as the current inflation rate.[28] This is an issue of fact for the forecasted costs in the MYP because inflation has declined significantly in 2023 relative to 2021 and 2022 and consensus economists' forecasts for future inflation are lower than current rates of inflation. The current inflation rate is often described as a ceiling for the LRP, therefore it is important to ensure Pepco's forecasted costs reflect up to date inflation estimates.

> In terms of the financial plan, spending targets are set in order to achieve operational goals, to comply with regulatory requirements, and to ensure that overall O&M increases are lower than the rate of inflation, which helps mitigate customer bill impact.[29]

[26] Exhibit PEPCO (G), Barnett Direct at 11-12.

[27] Exhibit PEPCO (A), O'Donnell Direct at 32.

[28] Exhibit PEPCO, Leming Direct at 6.

[29] Exhibit PEPCO (G), Barnett Direct at 11.

Q. DID YOU ASK ABOUT PEPCO ABOUT THE BASIS FOR ITS INFLATION ASSUMPTIONS IN DISCOVERY?

A. Yes. Pepco stated in discovery that, "when developing estimates of growth and inflation, Pepco leveraged the IHS Macro 10-year Baseline Consumer Price Index ('CPI') annual percent change from 2023-2026 as well as factored in recent inflation levels, which were in excess of this average."[30] Figure 1 shows Pepco's inflation estimates.

FIGURE 1[31]

Inflation Assumptions

	Assumption *(annual %)*	2023 LRP	2024 LRP	2025 LRP	2026 LRP
1	Default Inflation Rate (1)	3.9%	2.2%	2.1%	2.2%

Labor Rate Assumptions

	Labor Rate Assumption *(annual %)*	2023 LRP	2024 LRP	2025 LRP	2026 LRP
2	Salary Inflation Rate (average)	4.00%	3.00%	3.00%	3.00%
3	Hourly Non-Represented Inflation Rate (average)	4.00%	3.00%	3.00%	3.00%

NOTES
1. IHS U.S. Macro 10-Year Baseline Consumer Price Index [2022 September Vintage/Release]. Annual percent change

Pepco states it "factored in recent inflation levels" in its MYP forecast. However, it is important to note that inflation has decreased significantly since the Company developed its LRP. According to the *Blue Chip Financial Forecasts*, inflation was 3.2% in Q3 2023

30 Pepco's response to Data Request OPC 13-16, provided in Exhibit OPC (B)-4.

31 *Id.*

and expected to be 3.1% in Q4 2023.[32] However, inflation is forecasted to decline to about 2.4% through 2024.[33] This is a significant decrease from the 6.7% inflation Pepco cites in its testimony and Pepco has not demonstrated that its proposal is reasonable in light of this material change.

Importantly, Pepco's 2023 inflation forecast exceeded actual inflation in 2023. As discussed below, I believe this inflation estimate is one of the reasons for the significant 9.23% O&M increases Pepco assumes for 2023 and that inflates subsequent years in the MYP.

Q. DID PEPCO FORECAST A SIGNIFICANT INCREASE IN O&M COSTS IN THE MYP'S 2023 "BRIDGE" YEAR?

A. Yes. I provide an overview of Pepco's O&M expenses from 2018 through 2026 by account as my Exhibit OPC (B)-7. I also provide the labor and non-labor breakout of Pepco's O&M costs from 2018 to 2026 as Exhibit OPC (B)-8. The data is provided at the total distribution level rather than the DC distribution level because Pepco responded in discovery that it did not have the labor and non-labor O&M expenses at the DC jurisdictional level.

Table 6 summarizes the total distribution O&M expenses shown on Exhibit OPC (B)-8.

---

32 *Blue Chip Financial Forecasts*, October 2, 2023, at 2.

33 *Blue Chip Financial Forecasts*, October 2, 2023, at 2.

TABLE 6

Total Distribution O&M Expense
($ Millions)

		Labor O&M		Non-Labor O&M		Total O&M	
Line	**Description**	**Amount (1)**	**% Change (2)**	**Amount (3)**	**% Change (4)**	**Amount (5)**	**% Change (6)**
1	2018	$ 111.0		$ 293.9		$ 404.9

Source:
Exhibit OPC (B)-8.

As shown above, Pepco's total distribution O&M expenses are expected to increase by $41.2 million between the end of the 2022 historical test year and the end of the MYP. This cost increase can be attributed entirely to outside services, which is expected to increase by $41.0 million over the same time period, as shown on line 34 of Exhibit OPC (B)-7. This is by far the single biggest cost increase. No other account is forecasted to increase by over $10 million over this same time period.

A significant driver of Pepco's forecasted O&M increases is the PHISCO and Exelon Business Services Company ("BSC") costs allocated to Pepco. Pepco estimates that the PHISCO allocated labor costs will increase by $10.6 million between 2022 and the end of the MYP, and the BSC allocated labor costs will increase by $17.4 million in that same period. These service company labor costs are shown in Table 7, below.

TABLE 7

Total Distribution Service Company Labor Costs
($ Millions)

		PHISCO Allocated to Pepco		BSC Allocated to Pepco		Total Allocated to Pepco	
Line	**Description**	**Amount (1)**	**% Change (2)**	**Amount (3)**	**% Change (4)**	**Amount (5)**	**% Change (6)**
1	2018	$ 29.1		$ 17.4		$ 46.5	
2	2019	30.2	4.0%	18.7	7.2%	48.9	5.2%
3	2020	28.3	-6.3%	19.7	5.5%	48.0	-1.8%
4	2021	29.6	4.7%	19.0	-3.7%	48.6	1.2%
5	2022	29.4	-0.9%	21.1	11.0%	50.4	3.8%
6	2023	35.9	22.2%	34.2	62.4%	70.1	39.0%

Source:
Exhibit OPC (B)-8.

Both Table 6 and Table 7 show that Pepco assumes a significant increase in costs during the 2023 bridge year. Again, part of this increase may be attributable to Pepco's excessive and unreasonable inflation assumption for 2023.

Q. PLEASE DESCRIBE PHISCO AND BSC.

A. Pepco Witness Barnett summarizes the relationship between the various companies on pages 3-4 of his direct testimony:

> Exelon and PHI merged in 2016 with the District of Columbia Public Service Commission's authorization in Order No. 18148. PHI is a limited liability company and an indirect, wholly owned subsidiary of Exelon. PHI is comprised of PHISCO and three regulated utilities: Pepco, ACE, and DPL. PHISCO is a subsidiary of PHI. PHISCO provides a variety of shared services pursuant to service agreements with PHI's three regulated subsidiaries, Pepco, ACE, and DPL. Exelon also operates the Business Services Company (BSC), a separate shared service company. Similar to

> PHISCO, BSC provides services to PHISCO, Pepco, ACE, and DPL pursuant to service agreements. BSC is a subsidiary of Exelon. Both PHISCO and BSC are also responsible for delivering specific, unique shared services to Pepco.[34]

Mr. Barnett explains on pages 5-6 of his direct testimony how the services provided by PHISCO and BSC differ. CONFIDENTIAL Exhibit PEPCO (B)-9 includes the Cost Accounting Manual ("CAM") and General Services Agreement ("GSA") which cover the allocation of the service company costs to Pepco.

My Exhibit OPC (B)-9 provides the historical charges for PHISCO and BSC to each of their affiliates as reported on the FERC Form 60. As shown on my exhibit, the BSC costs allocated to Pepco in particular saw a large increase in 2022 despite total charges across all affiliates decreasing by 17% that year. The decrease was largely due to Exelon completing the spin-off of its generation business on February 1, 2022.

It is necessary to take a fresh look at the affiliate allocation factors as the BSC client companies change to ensure that the costs being allocated to the DC jurisdiction are being fairly calculated. Pepco's MYP testimony has not provided this level of transparency into its allocation factors. Pepco has not developed the factual support necessary to prove the reasonableness of its projections.

Q. DID PEPCO JUSTIFY THE SIGNIFICANT INCREASE IN ALLOCATED SERVICE COMPANY FEES SHOWN IN TABLE 6 AND TABLE 7, ABOVE?

A. No. Pepco Witnesses Barnett, Vavala, and Bell-Izzard support O&M costs at the management view, or line 1 on my Table 5. They do not adequately describe what

34 Exhibit PEPCO (G), Barnett Direct at 3-4.

additional services Pepco's DC operations are expected to receive from PHISCO and BSC that justify the significant cost increases, nor do they argue the service company charges are being correctly allocated to Pepco. Mr. Barnett does note when discussing the 2023 non-IT increases in BSC costs that the increase includes, "higher inflation costs, annual merit increases, insurance premiums, and cybersecurity costs as well as higher staffing and recruitment costs…"[35] However, Mr. Barnett does not state what inflation estimate he is using for 2023 nor what additional services the additional staff will be providing Pepco. Pepco's failure to provide these key details undermines the reliability of its projections.

Mr. Leming supports the allocation of service company fees to Pepco but he does not provide workpapers supporting the allocation of PHISCO and BSC costs to Pepco relative to other affiliates. Mr. Leming provides CONFIDENTIAL Exhibit PEPCO (B)-9 but this exhibit only describes the allocation process and does not support the actual allocation factors used to allocate costs to Pepco.

Q. WHAT DO YOU RECOMMEND?

A. Given Pepco's failure to provide factual or analytical support for the significant increase in service company charges, I recommend the Commission limit the amount of these charges in the MYP pending justification from Pepco that includes a full accounting of the allocated costs, reasons for the increase, support for each allocation factor used to allocate costs from PHISCO and BSC, how that allocation compares to other PHISCO and BSC affiliates, and evidence that the service company charges paid by Pepco are no more than

[35] Exhibit PEPCO (G), Barnett Direct at 36.

those that would be charged by an independent third party. I recommend the Commission cap the service company charges at the 2023 bridge year level. As shown in my Table 8, below, this still reflects a significant increase over Pepco's actual 2022 expenses. Capping these costs at the forecasted 2023 level will lower the total distribution O&M expense during the MYP by $3.6 million in 2024, $6.4 million in 2025 and $8.3 million in 2026. The DC distribution impact is $1.6 million in 2024, $2.8 million in 2025, and $3.7 million in 2026. My adjustment is included as Exhibit OPC (B)-10.

TABLE 8

Service Company Charges Adjustment
($000)

Line	Year	PHISCO Allocated to Pepco (1)	BSC Allocated to Pepco (2)	Total Charges (3)	Adjustment (4)	Revised Total Charges (5)
1	2022	$ 29,361	$ 21,053	$ 50,414		$ 50,414
2	2023	35,871	34,197	70,069		70,069
3	2024	37,367	36,312	73,679	(3,611)	70,069
4	2025	38,921	37,562	76,483	(6,414)	70,069
5	2026	39,928	38,435	78,363	(8,294)	70,069

Source:
Exhibit OPC (B)-10.

Q. IS THERE ADDITIONAL EVIDENCE THAT CAPPING THESE COSTS AT THE MYP'S 2023 BRIDGE YEAR AMOUNT IS A REASONABLE ADJUSTMENT?

A. Yes. Pepco's TTY compliance filing shows that the 2023 service company labor costs are expected to be $64.9 million compared to the $70.1 million shown above in Table 8.[36] Assuming the updated cost estimate of $64.9 million for these allocated labor costs was escalated at a 2.5% inflation rate each year then the costs during the MYP would still be below my proposed cap of $70.1 million.

C. Deficient Deferred Income Taxes

Q. PLEASE DESCRIBE PEPCO'S PROPOSAL REGARDING ITS DEFICIENT DEFERRED INCOME TAXES ("DDIT").

A. Pepco Witness Leming discusses the Company's DDIT proposal in his direct testimony. He also includes a DDIT adjustment as Ratemaking Adjustment ("RMA") 15. Pepco re-measured its accumulated deferred income tax ("ADIT") balance as a result of the 2017 Tax Cuts and Jobs Act ("TCJA"). The presence of Excess deferred income taxes ("EDIT") or DDIT is the result of differences between deferred taxes at the old federal income tax rate and the new rate. EDIT represents an over-collection of deferred tax payments from customers that will not be remitted to government taxing authorities due to the TCJA. DDIT are an under-collection.

---

[36] Pepco's response to Data Request OPC 13-4, provided in Exhibit OPC (B)-4.

Mr. Leming explains that property-related deferred tax differences are typically the result of accelerated tax depreciation versus straight-line depreciation timing differences.[37] The TCJA created EDIT for Pepco's property-related deferred tax liabilities. Mr. Leming goes on to explain that non-property related deferred income tax differences are typically the result of payroll related timing differences.[38] The TCJA created DDIT for Pepco's non-property related deferred tax assets because the value of the deferred tax assets was re-measured downward. The DDIT balance is for PHISCO. A portion of the DDIT balance was allocated to Pepco consistent with the Company's cost allocation methodologies.

Pepco proposes to amortize the non-property related DDIT over five years in its MYP application. This adjustment is included as RMA-15. The adjustment increases Pepco's revenue deficiency by $1.579 million in 2024, $1.489 million in 2025, and $1.398 million in 2026.

Q. HAS THE COMMISSION RULED ON RECOVERY OF THIS DDIT FROM CUSTOMERS?

A. Yes. In FC 1156, the Commission approved the amortization of Pepco's EDIT but denied an amortization of Pepco's share of PHISCO's DDIT. The Commission concluded in Order No. 20755:

> The Commission agrees with OPC's position that while the PHISCO plant assets and property related ADIT balances are authorized in rate base, the PHISCO non-property related ADIT balances are not. Pepco contended that the test should be whether the underlying basis is included in customer rates as a recoverable operating expense since there are underlying tax basis accounts that are not included in Pepco's ADIT in rate base but were

[37] Exhibit PEPCO (B), Leming Direct at 57.

[38] Exhibit PEPCO, Leming Direct at 57.

> included in Pepco's non-property EDIT agreed to in Formal Case No. 1150. However, the Commission denies the Company's revised proposal to include the NPNP DDIT asset of $5.853 million on a gross basis. The Company's reference to the EDIT Settlement agreement is misplaced. The NP EDIT agreed to in Formal Case No. 1150 did not address the PHISCO deferred income tax balances; it only addressed the Pepco balances. PHISCO non-property ADIT is not a component of rate base.[39]

Q. WHY DOES MR. LEMING BELIEVE THE COMMISSION SHOULD REVERSE ITS DECISION FROM FC 1156?

A. Mr. Leming offers two reasons why the Commission should reverse its decision. However, his reasoning does not justify a change from the Commission finding in FC1156.

Q. PLEASE EXPLAIN.

A. First, Mr. Leming notes that the DDIT was approved for recovery in Maryland Public Service Commission Case No. 9602 in Order No. 89227[40] issued on August 12, 2019. This Maryland decision was before the DC Commission's decision in FC1156 that was issued on June 8, 2021. The Maryland Order was available at the time the FC 1156 decision was entered and does not constitute new information.

Second, Mr. Leming argues that because the underlying costs giving rise to PHISCO's non-property related DDIT is included in customer rates, the corresponding DDIT should also be included cost of service.[41] Again, this is not new information. More importantly, the Commission considered and rejected this argument from Pepco in FC 1156: "Pepco contended that the test should be whether the underlying basis is included

---

[39] FC1156 Order and Opinion No. 20755, June 8, 2021, page 136.

[40] Pepco (B), Leming Direct at 59.

[41] Pepco (B), Leming Direct at 59.

in customer rates as a recoverable operating expense..."[42] Pepco provides no basis for reversing this rationale and reaching a different conclusion in this proceeding.

Q. WHAT IS YOUR RECOMMENDATION?

A. Consistent with prior findings, I recommend Pepco's proposed RMA-15 pro forma adjustment be removed from the MYP projected cost of service. As shown on my summary exhibit, removing. Pepco's RMA-15 reduces the Company's revenue deficiency by $1.579 million in 2024, $1.489 million in 2025, and $1.398 million in 2026.

D. COVID-19 Cost Recovery

Q. PLEASE DESCRIBE PEPCO'S PROPOSAL REGARDING THE RECOVERY OF ITS COVID-19 RELATED INCREMENTAL COSTS DURING THE MYP.

A. In Order No. 20329 the Commission directed Pepco to create a regulatory asset for incremental costs related to COVID-19 that could be considered for recovery in a future base rate case. Pepco states it deferred prudently incurred incremental costs related to COVID-19 between March 11, 2020 and August 8, 2021. The deferred costs include incremental lost late payment revenues, incremental lost connection and reconnection fees, and pandemic-related incremental equipment, cleaning, and other costs. The COVID-19 costs also includes the incremental increase in bad debt expense. Pepco also recorded cost offsets such as reduced meals, travel and other costs.

[42] FC1156 Order and Opinion No. 20755, June 8, 2021, page 136.

Pepco proposes to recover the COVID-19 over five years. This regulatory asset increases Pepco's revenue requirement by $3.441 million in 2024, $3.244 million in 2025, and $3.046 million in 2026.

Q. DO YOU HAVE ANY CONCERNS WITH PEPCO'S PROPOSAL?

A. Yes. I believe the Commission should consider approving a longer amortization period given the extraordinary and non-recurring nature of this cost. The pandemic is not expected to be repeated and is therefore a once in a lifetime non-recurring event. The rate impact of this COVID event should be mitigated as much as possible in this case. I recommend a six-year amortization period be used for either the MYP or TTY cost of service. A typical rate case cycle is two or three years. A six-year recovery period will align recovery of the COVID-19 costs with two to three traditional rate case cycles if Pepco files a rate case every two to three years. I believe a six-year recovery is more appropriate than a five-year recovery because extending the recovery period will mitigate the rate increase proposed by Pepco without harming the Company's ability to recover these costs while still allowing the Company to recovery these costs over the same two to three traditional rate case cycles. Pepco stated in discovery the Commission has approved various regulatory asset amortization periods ranging from 3 years to 15 years.[43]

The adjustment to reflect a six-year recovery of the pandemic-related costs is included in my Exhibit OPC (B)-11. Recovering the COVID-19 costs over the Company's

[43] Pepco's response to Data Request OPC 13-33, provided in Exhibit OPC (B)-4.

next two MYPs will lower the Company's revenue requirement by approximately $408,000 in 2024, $375,000 in 2025, and $342,000 in 2026.

Q. DO YOU RECOMMEND OTHER REGULATORY ASSETS BE RECOVERED OVER SIX YEARS?

A. Yes. Pepco has four other MYP RMAs that propose a five-year amortization. Aligning these amortization periods with two to three traditional rate case cycles helps alleviate some of the revenue deficiency in this case while limiting cost recovery to the same two or three rate case cycles. My adjustment is included in Exhibit OPC (B)-11. Combined with my COVID-19 adjustment, the longer amortization periods lower Pepco's claimed revenue deficiency by approximately $553,000 in 2024, $510,000 in 2025, and $471,000 in 2026.

V. <u>TRADITIONAL TEST YEAR REVENUE REQUIREMENT ADJUSTMENTS</u>

Q. PLEASE BRIEFLY SUMMARIZE YOUR PROPOSED ADJUSTMENTS TO PEPCO'S TTY REVENUE REQUIREMENTS?

A. I recommend several adjustments to Pepco's TTY revenue requirement, as shown on Table 2 above.

- Pepco's TTY Compliance filing includes several adjustments to annualize expenses for the end of the test year but the Company does not annualize revenues to account for customer growth during the test year. I recommend Pepco's TTY revenues be adjusted to reflect the number of customers at the end of 2023.

- Pepco is requesting authority from the Commission to recover its deficient deferred income taxes just as the Company did in FC 1156. Given Pepco has offered no new evidence that would suggest the Commission reverse its decision from the prior case, I recommend these costs be removed from cost of service.

- Pepco is requesting to recover several of its regulatory assets, including the deferred COVID-19 costs, over five years. Given the extraordinary nature of the pandemic, I recommend the COVID-19 costs be recovered over a longer period of time, or six years.

- Pepco's TTY Compliance filing includes an inflation adjustment to non-labor O&M expense. However, Pepco's adjustment uses an inflation rate that is excessive compared to actual inflation in 2023. Therefore, I recommend Pepco's adjustment be adjusted to reflect actual inflation in the second half of 2023.

A. 2023 Sales Revenues

Q. HOW DOES PEPCO FORECAST ITS REVENUES FOR THE TTY?

A. Pepco assumes $671,304,428 of electricity sales in its 2023 TTY. As shown on Pepco's Voluntary DR 1-01, Attachment A14 (provided in Exhibit OPC (B)-4) this assumption includes six months of actual sales and six months of forecasted sales. Pepco makes one ratemaking adjustment to its TTY revenues. RMA 13 removes from the TTY revenues the five-year EDIT credits that will sunset during the test period.

Q. DID PEPCO PROJECT TTY REVENUE SALES FOR ITS TRADITIONAL COST OF SERVICE IN A SIMILAR WAY THAT IT PROJECTED RATE BASE AND O&M EXPENSES?

A. No. In projecting test year sales, the Company relied on actual sales within the test year. However, for projecting rate base and O&M expenses, the Company adjusted these items for end-of-year growth in plant investment and operating expenses. Hence, there is a mismatch in the way the Company developed its revenue projections for the historical test year and the manner in which it is projecting rate base and O&M expenses for the same time period. For example, Pepco uses a year end rate base. Mr. Leming argues using a year-end rate base is more appropriate in his October 2023 supplemental direct testimony.

> RMA 4 annualizes the difference in rate base that results from using a 13-month average balance for the cost of service rather than the year-end balance. The year-end balance provides a better picture of the used and useful investments that serve customers during the rate effective period. The 13-month average balance understates the Company's true cost of service for these investments, which in turn, limits the Company from earning a reasonable authorized return on these investments.[44]

Pepco elaborated on its position in discovery:

> When setting rates based on a traditional test period, the year end balances for that test period would be used and useful in providing service to customers in each month of the rate effective period. Said another way, an asset placed in-service in December 2023 would be used and useful in every month in 2024 when rates in this proceeding are anticipated to go into effect. If that asset were to be treated on a 13-month average basis, that asset would only be reflected in 1-month of the 13-month average from December 2022 through December 2023. This means that customers' rates would only reflect a small fraction of the annual cost of service related to this asset, while it is used and useful in providing service in each month of the rate effective period. This has the effect of drastically understating the true cost of service for this asset.[45]

This same principle also applies to Pepco's revenues. Pepco not making an adjustment to annualize revenues to account for the increase in customers during the TTY results in the Company understating revenue and inflating the claimed revenue deficiency. Further, Pepco adjusted operating expenses including depreciation expense for end-of-year items.[46] Adjusting operating expenses to year end, decreases operating income and increases the

---

[44] Exhibit PEPCO (2B), Leming October 2023 Supplemental Direct at 11.

[45] Pepco's response to Data Request OPC 13-14, provided in Exhibit OPC (B)-4.

[46] Exhibit PEPCO (2B), Leming October 2023 Supplemental Direct at 10.

estimated revenue deficiency. Conversely, adjusting customers to year end, increases operating, and reduces the revenue deficiency. If yearend adjustments are allowed, all adjustment to historical year data are needed to properly match historical revenue and expenses based on historical year-end data. This produces the most accurate and reliable estimated of the ability of current rates to recover Pepco's cost of service in the rate effective period.

Pepco explained why it did not make a year-end adjustment to revenues in discovery:

> Calculating test year base distribution revenues based on year-end customer counts would improperly over- or under-state the revenues for each rate class that the Company is allowed during the test year and would be inconsistent with prior traditional test year rate cases.[47]

Pepco is incorrect for the reasons I stated above.

Q. HOW SHOULD REVENUES FOR THE TEST YEAR BE ADJUSTED TO REFLECT END-OF-YEAR RATE BASE AND OPERATING EXPENSES?

A. Test year revenues should be adjusted to reflect end-of-year growth in number of customers that occurred throughout the test year. This will result in an increased level of annual sales due to an increased level of number of customers taking service at year-end, compared to the average number of customers throughout the year.

Pepco forecasts it will have 395,386 customers in December 2023, or an increase of 4,989 customers, or 1.3%.[48] The increase in sales revenues associated with customers

[47] Pepco's response to Data Request OPC 14-4, provided in Exhibit OPC (B)-4.

[48] Exhibit PEPCO 2(E)-1.

growth will provide Pepco increased revenue to pay for its projected increase to year-end rate base and O&M expense in the test year.

Q. WHAT DO YOU RECOMMEND?

A. I recommend the TTY revenues be annualized to reflect the year end number of customers. My adjustment is included as Exhibit OPC (B)-12. My adjustment increases the TTY revenues by approximately $1.1 million. My adjustment relied on the monthly BSA revenue per customer targets and the December 2023 number of customer provided as part of Exhibit PEPCO 2(E).

B. Deficient Deferred Income Taxes

Q. ARE YOU PROPOSING AN ADJUSTMENT TO PEPCO'S DDIT IN THE TTY?

A. Yes. I recommend the DDIT be excluded from cost of service for the same reasons I discussed above. This adjustment lowers the TTY revenue requirement by $1.5 million.

C. COVID-19 Cost Recovery

Q. ARE YOU PROPOSING A SIMILAR COVID-19 ADJUSTMENT TO THE COMPANY'S TTY COMPLIANCE FILING?

A. Yes. Given the extraordinary nature of the pandemic I believe a longer recovery period is appropriate. As discussed above, rate cases are typically filed every two to three years. A six-year amortization period is preferable to a five-year amortization period because it mitigates the rate increase proposed in this proceeding while limiting cost recovery to the same two to three traditional rate cycles that would be applicable to a five-year amortization. My adjustment to the compliance filing is included as Exhibit OPC (B)-13 and reflects a six-year amortization. This adjustment reduces the TTY revenue deficiency by approximately $412,000. Adjusting the other two RMA regulatory assets in the TTY that Pepco proposes to recover over five years to six years increases the total adjustment to approximately $500,000.

D. Inflation Adjustment

Q. DOES PEPCO INCLUDE AN INFLATION ADJUSTMENT TO ITS O&M IN ITS TTY COST OF SERVICE?

A. Yes. Pepco's TTY Compliance filing includes an inflation adjustment to non-labor O&M expense (RMA 34). Pepco uses a 3.63% annual inflation rate based on a five-year historical average inflation rate. This inflation rate is overstated compared to the actual inflation rate in the second half of 2023 and an independent economist forecasted inflation rate for 2024.

Pepco's TTY uses a test year ending December 31, 2023 that includes six months of actual data and six months of forecasted data. According to the *Blue Chip Financial Forecasts,* inflation was 3.2% in Q3 2023 and expected to be 3.1% in Q4 2023. Inflation is forecasted to be about 2.4% in 2024. Pepco's inflation estimate in the TTY of 3.63% (see RMA 34) should be revised to reflect the consensus analysts' estimate of 3.2%, and to be in effect for the six-month projection period. This adjustment lowers Pepco's TTY revenue requirement by approximately $384,000. My adjustment is included as Exhibit OPC (B)-14.

VI. BILL STABILIZATION ADJUSTMENT ("BSA")

Q. DOES PEPCO INCLUDE THE BSA REGULATORY ASSET DEFERRAL IN ITS TTY COST OF SERVICE?

A. Yes. As part of its TTY compliance filing the Company is requesting a return on its BSA deferral balance. The current balance of the deferral is $113.781 million. Pepco's proposal stems from a finding in an independent audit requested by the Commission in Order No. 20755. The Atrium Economics final audit report was issued in July 2023, or after the Company's MYP filing in April 2023. Among other findings, the report recommended the Commission consider credit-supportive measures due to the deferral.

> In response to the financial concerns addressed in F-2.3 (7), Atrium recommends that the Commission continue to monitor Pepco's credit quality for signs of deterioration and consider implementing credit support measures such as allowing a return on the BSA deferral balance or increasing ROE to account for under-earnings associated with the BSA balance, should circumstances warrant such support. [R-2.3(2)][49]

Ms. O'Donnell agreed with Atrium Economics' recommendation in her October 2023 direct testimony.

> **Q. Does the Company agree that a return on the BSA 1 deferral balance is warranted and is it included in the TTYCF?**
>
> A10. Yes, as discussed in my Direct Testimony (page 40), a large deferral balance and the associated unrecovered carrying costs put additional cash flow burden on the Company and negatively impacts Pepco's Generally Accepted Accounting Principles (GAAP) earned ROE. The approval of the Company's proposed MYP, and an update to the Company's billing determinants, will improve the overall financial health of the Company and its credit metrics, reducing borrowing costs, which leads to lower customer rates. The Company has included a ratemaking adjustment (RMA) to reflect

[49] Atrium Economics Final Audit Report, July 7, 2023.

the BSA regulatory asset deferral balance in rate base for the TTYCF.

Mr. Leming supports the Company's RMA 12 which adds the BSA deferral balance as a regulatory asset in rate base.

Q. DO YOU BELIEVE PEPCO IS ENTITLED TO EARN A RETURN ON ITS BSA DEFERRAL BALANCE?

A. No. Pepco acknowledged in its April 2023 MYP filing that the Company is not currently authorized to earn a return on the BSA deferral balances.[50] Furthermore, Pepco has not shown a need to earn a return on the BSA deferral balance as part of its TTY and a reason to reverse the current policy regarding a return. Ms. O'Donnell argues in her October 2023 supplemental direct testimony that, "the approval of the Company's proposed MYP, and an update to the Company's billing determinants, will improve the overall financial health of the Company and its credit metrics..."[51] The same is true for the TTY. While Pepco has argued the BSA is one of the reasons it has not previously earned its authorized ROE[52], the updated rates and billing determinants approved in this proceeding will give Pepco the opportunity to earn its authorized ROE even without a return on the BSA deferral balances.

---

[50] O'Donnell Direct at 40.

[51] O'Donnell October 2023 Supplemental Direct at 5.

[52] Barnett Direct at 56. Mr. Barnett argues, "Approximately $9 million (pre-tax) in unrecoverable carrying costs reduces Pepco's earned GAAP ROE reported to investors. For perspective, had the BSA deferral balance been included in rate base, it would have reduced Pepco DC's ratemaking ROE by approximately 55 basis points (bps) in 2022."

Q. WHAT IS THE REVENUE REQUIREMENT IMPACT OF REMOVING THE BSA REGULATORY ASSET FROM THE TTY RATE BASE?

A. I include this adjustment as my Exhibit OPC (B)-15. Removing the BSA regulatory asset from rate base lowers the Company's TTY revenue deficiency by approximately $10.3 million.

Q. ASSUMING THE COMMISSION ALLOWS THE COMPANY TO EARN A RETURN ON THE BSA REGULATORY ASSET, HAS PEPCO ACCURATELY ESTIMATED THE IMPACT ON THE TTY RATE BASE?

A. No. Pepco did not adjust the BSA regulatory asset to remove income taxes included in the uncollected revenue that is recorded in the BSA regulatory asset. The income tax expense associated with uncollected revenue will not become taxable income until the Company recovers the BSA revenue from customers. Hence, the BSA regulatory asset should be reduced by the income tax included in the uncollected BSA revenue, and a carrying charge should only apply to the after-tax balance of the BSA regulatory asset. The full value of the BSA asset should be collected as the asset is amortized.

Q. DOES THIS COMPLETE YOUR PREFILED DIRECT TESTIMONY?

A. Yes, it does.

A. Michael P. Gorman. My business address is 16690 Swingley Ridge Road, Suite 140, Chesterfield, MO 63017.

Q. PLEASE STATE YOUR OCCUPATION.

A. I am a consultant in the field of public utility regulation and a Managing Principal with the firm of Brubaker & Associates, Inc. ("BAI"), energy, economic and regulatory consultants.

Q. PLEASE SUMMARIZE YOUR EDUCATIONAL BACKGROUND AND WORK EXPERIENCE.

A. In 1983 I received a Bachelor of Science Degree in Electrical Engineering from Southern Illinois University, and in 1986, I received a Master's Degree in Business Administration with a concentration in Finance from the University of Illinois at Springfield. I have also completed several graduate level economics courses.

In August of 1983, I accepted an analyst position with the Illinois Commerce Commission ("ICC"). In this position, I performed a variety of analyses for both formal and informal investigations before the ICC, including: marginal cost of energy, central dispatch, avoided cost of energy, annual system production costs, and working capital. In October of 1986, I was promoted to the position of Senior Analyst. In this position, I assumed the additional responsibilities of technical leader on projects, and my areas of responsibility were expanded to include utility financial modeling and financial analyses.

In 1987, I was promoted to Director of the Financial Analysis Department. In this position, I was responsible for all financial analyses conducted by the Staff. Among other things, I conducted analyses and sponsored testimony before the ICC on rate of return, financial integrity, financial modeling and related issues. I also supervised the development of all Staff analyses and testimony on these same issues. In addition, I supervised the Staff's review and recommendations to the Commission concerning utility plans to issue debt and equity securities.

In August of 1989, I accepted a position with Merrill-Lynch as a financial consultant. After receiving all required securities licenses, I worked with individual investors and small businesses in evaluating and selecting investments suitable to their requirements.

In September of 1990, I accepted a position with Drazen-Brubaker & Associates, Inc. ("DBA"). In April 1995, the firm of Brubaker & Associates, Inc. was formed. It includes most of the former DBA principals and Staff. Since 1990, I have performed various analyses and sponsored testimony on cost of capital, cost/benefits of utility mergers and acquisitions, utility reorganizations, level of operating expenses and rate base, cost of service studies, and analyses relating to industrial jobs and economic development. I also participated in a study used to revise the financial policy for the municipal utility in Kansas City, Kansas.

At BAI, I also have extensive experience working with large energy users to distribute and critically evaluate responses to requests for proposals ("RFPs") for electric, steam, and gas energy supply from competitive energy suppliers. These analyses include the evaluation of gas supply and delivery charges, cogeneration and/or combined cycle unit feasibility studies, and the evaluation of third-party asset/supply management agreements. I have participated in rate cases on rate design and class cost of service for electric, natural gas, water and wastewater utilities. I have also analyzed commodity pricing indices and forward pricing methods for third party supply agreements, and have also conducted regional electric market price forecasts.

In addition to our main office in St. Louis, the firm also has branch offices in Corpus Christi, Texas; Detroit, Michigan; Louisville, Kentucky and Phoenix, Arizona.

Q. HAVE YOU EVER TESTIFIED BEFORE A REGULATORY BODY?

A. Yes. I have sponsored testimony on cost of capital, revenue requirements, cost of service and other issues before the Federal Energy Regulatory Commission and numerous state regulatory commissions including: Alaska, Arkansas, Arizona, California, Colorado, Delaware, the District of Columbia, Florida, Georgia, Idaho, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Montana, Nevada, New Hampshire, New Jersey, New Mexico, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, South Carolina, South Dakota, Tennessee, Texas, Utah, Vermont, Virginia, Washington, West Virginia, Wisconsin, Wyoming, and before the provincial regulatory boards in Alberta, Nova Scotia, and Quebec, Canada. I have also sponsored testimony before the Board of Public Utilities in Kansas City, Kansas; presented rate setting position reports to the regulatory board of the municipal utility in Austin, Texas, and Salt River Project, Arizona, on behalf of industrial customers;

and negotiated rate disputes for industrial customers of the Municipal Electric Authority of Georgia in the LaGrange, Georgia district.

Q. PLEASE DESCRIBE ANY PROFESSIONAL REGISTRATIONS OR ORGANIZATIONS TO WHICH YOU BELONG.

A. I earned the designation of Chartered Financial Analyst ("CFA") from the CFA Institute. The CFA charter was awarded after successfully completing three examinations which covered the subject areas of financial accounting, economics, fixed income and equity valuation and professional and ethical conduct. I am a member of the CFA Institute's Financial Analyst Society.

Formal Case No. 1176
Pepco's Responses to Data Requests
Referenced in the Direct Testimony
<u>of OPC Witness Michael P. Gorman</u>

<u>Pepco's Responses to Data Requests</u>: **<u>Page</u>**

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO AOBA DATA REQUEST NO. 1

QUESTION NO. 11
Re: Exhibit Pepco (A), page 10, lines 15-17. Please:

a. Provide the Company's forecasts of the "growth in electrification" it antici-pates within each year of its current planning horizon, as well as the workpapers, analyses, data, studies, and other documents relied upon to make such forecasts for its District of Columbia distribution system.
b. Detail the impacts of the referenced "growth in electrification" on the Company's forecasted units of service (i.e., customers, kWh deliveries, and kW demands by rate class) for each year of the Company's proposed multi-year rate plan.
c. Provide the Company's forecasts by year of the numbers of current users of gas heating customers heating systems that the Company expects to convert from gas service to electric service.

RESPONSE:

a. Currently, the Company does not directly include electrification into its 10-year capacity/load forecasts. While identified and specific near-term usage and planned capacity additions have been incorporated, electrification has not been projected at levels that would be required to meet the District's anticipated goals for electrification.

   For a detailed explanation of the Company's capacity planning forecasting and methodology, please see PEPCO (H)-1, Chapter 1 entitled "Load Growth."

b. Please see Pepco's response to part (a) and note that, for distribution system planning purposes, as identified in the question, Pepco does not perform detailed analyses down to the rate class level regarding forecasted units of service.

c. Pepco has not included conversions of gas heat to electrical heating sources in its most recent Ten-Year Forecast.

SPONSOR: Jaclyn Cantler

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO DCG DATA REQUEST NO. 1

QUESTION NO. 4
Refer to Pepco Response to AOBA Data Request No. 11-1(a). If Pepco does not directly include electrification into its 10-year capacity/load forecasts, explain why "proposed investments in this MYP are fundamental to preparing the grid for customer adoption of electrification in the near-term" as stated in the Direct Testimony of Witness O'Donnell at page 10.

RESPONSE:

The Company assumes that the question meant to reference Pepco's response to AOBA 1-11(a). The Company does not forecast electrification separately from other load, at this time, as noted in the response to 1-11(a). However, the Company does incorporate near term usage when available.

The proposed investments in this MYP are fundamental to preparing the distribution system because the distribution system needs to operate efficiently and effectively, especially with the growth in electrification that will be required to advance the District's decarbonization and clean energy goals. As noted in Witness O'Donnell's testimony (page 10, line 17-20) As customers increase their use of electricity at homes and businesses across the District, it will be even more vital that the grid function smoothly and provide consistent, reliable service.

SPONSOR: Elizabeth M. D. O'Donnell and Jaclyn Cantler

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO DCG DATA REQUEST NO. 4

QUESTION NO. 3
Answer the following related to Pepco's decision to use the Company's Long-Range Plan (LRP) for the projection of revenues and expenses instead of the index approach as approved in FC 1156 as described on pages 8-9 of the Direct Testimony of Witness Leming.

A. Have any of the parties to FC 1156 raised concerns with the level of transparency over the course of the Modified EMRP? If yes, explain the number of parties that raised concerns and the specific concerns.

B. Is it the Company's opinion that the use of an escalation factor approach is the reason it did not earn its authorized rate of return during the EMRP period? If no, explain all other contributing factors.

C. Explain how the LRP approach improves the Company's incentive to achieve cost-efficiencies compared to the index approach.

RESPONSE:

A. FC 1156 is an open docket and any concerns raised by parties in that proceeding are available for review on the Commission's website.

B. No. Please refer to the Company's response to DCG DR 3-11.

C. The LRP approach improves the Company's incentive to achieve cost efficiencies by aligning the baseline from which to seek efficiencies to the work it expects to perform, rather than a general inflation factor which may or may not correlate with the planned work in a given year.

SPONSOR: Robert T. Leming

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 3

QUESTION NO. 9
Provide normalized (weather-adjusted) electricity usage data by month for each current and proposed rate class for each of the years 2018 – 2022 and each month of 2023. Provide the source documents containing the usage data supplied in response to this request. Provide the requested documents in electronic form with all spreadsheet links and formulas intact, source data used, and explain all assumptions and calculations used. To the extent the data requested is not available in the form requested, provide the information in the form that most closely matches what has been requested. Please also provide the data used and estimation of weather normalized electricity usage for each rate class and for each year.

RESPONSE:

Please see FC 1176 OPC DR 3-9 Attachment.

SPONSOR: Matthew J. Bonikowski and Ekaterina Efimova

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 13

QUESTION NO. 1

Please provide a breakdown (in an electronic format) of the Company's operations and maintenance ("O&M") expenses in each of the last five years (2018 to 2022) by FERC account and split between labor and non-labor. Please present this information by total company and at the D.C. jurisdictional level.

RESPONSE:

The Company has not prepared the analysis in the format requested. For available information, please see FC 1176 OPC DR 13-1 Attachment which provides an O&M breakout for the requested years between labor and non-labor at the total Pepco Distribution level. This breakout is not available at the jurisdictional level as the Company allocates its costs based on FERC account but does not perform its jurisdictional allocation by expense type.

RESPONSE TO OPC DATA REQUEST NO. 13

QUESTION NO. 2

Please provide a breakdown (in an electronic format) of the Company's O&M expenses for the 2023 Bridge Year as shown on the Company's application for a Multiyear Rate Plan ("MYP") by FERC account and split between labor and non-labor. Please present this information by total company and at the D.C. jurisdictional level.

RESPONSE:

The Company has not prepared the analysis in the format requested. For available information, please see FC 1176 OPC DR 13-2 Attachment which provides an O&M breakout for the 2023 MYP Bridge Year between labor and non-labor at the total Pepco Distribution level. This breakout is not available at the jurisdictional level as the Company allocates its costs based on FERC account but does not perform its jurisdictional allocation by expense type.

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 13

QUESTION NO. 5
Please provide a breakdown (in an electronic format) of the Company's forecasted O&M expenses annually for 2024, 2025, and 2026 as included in the Company's application for an MYP by account and split between labor and non-labor. Please present this information by total company and at the D.C. jurisdictional level.

RESPONSE:

The Company has not prepared the analysis in the format requested. For available information, please see FC 1176 OPC DR 13-5 Attachment which provides an O&M breakout for the requested MYP years between labor and non-labor at the total Pepco Distribution level. This breakout is not available at the jurisdictional level as the Company allocates its costs based on FERC account but does not perform its jurisdictional allocation by expense type.

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 13

QUESTION NO. 14
Please refer to page 11 of Witness Leming's October 16, 2023 supplemental direct testimony, PEPCO (2B). Please explain why the Company proposes to use a year-end rate base to calculate its Traditional Test Year revenue requirement when the Company proposed to use a 13-month average rate base in its MYP. Please cite any Commission Orders that support the Company's answer.

RESPONSE:

As discussed in the referenced testimony passage, the year-end balance provides a better picture of the used and useful investments that serve customers during the rate effective period.

When setting rates based on a traditional test period, the year end balances for that test period would be used and useful in providing service to customers in each month of the rate effective period. Said another way, an asset placed in-service in December 2023 would be used and useful in every month in 2024 when rates in this proceeding are anticipated to go into effect. If that asset were to be treated on a 13-month average basis, that asset would only be reflected in 1-month of the 13-month average from December 2022 through December 2023. This means that customers' rates would only reflect a small fraction of the annual cost of service related to this asset, while it is used and useful in providing service in each month of the rate effective period. This has the effect of drastically understating the true cost of service for this asset.

In contrast, in an MYP the test periods used to set rates align with the rate effective period for those rates. Under this construct, if an asset is placed in service in December in 2024, it would only be used and useful in providing service to customers for 1-month out of that rate year. As such, it is more appropriate under an MYP to use a 13-month average rate base to determine revenue requirements as that appropriately reflects the portion of the year that those assets are being used to provide service to customers and appropriately states the cost of service in a given rate year.

DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 13

QUESTION NO. 16
Please provide all inflation estimates used in the Company's MYP. Please provide workpapers that support any estimates.

RESPONSE:

Pepco relied on labor rates of 3% as an assumption for 2024-2026 given the Company's internal corporate assumption book. A breakdown of this analysis is provided below. Pepco leveraged a non-labor inflation rate of 2.5% in the budgeting system. When developing estimates of growth and inflation, Pepco leveraged the IHS Macro 10-year Baseline Consumer Price Index (CPI) annual percent change from 2023-2026 as well as factored in recent inflation levels, which were in excess of this average.

Inflation Assumptions

	Assumption *(annual %)*	**2023 LRP**	**2024 LRP**	**2025 LRP**	**2026 LRP**
1	Default Inflation Rate (1)	3.9%	2.2%	2.1%	2.2%

Labor Rate Assumptions

	Labor Rate Assumption *(annual %)*	**2023 LRP**	**2024 LRP**	**2025 LRP**	**2026 LRP**
2	Salary Inflation Rate (average)	4.00%	3.00%	3.00%	3.00%
3	Hourly Non-Represented Inflation Rate (average)	4.00%	3.00%	3.00%	3.00%

NOTES
1. IHS U.S. Macro 10-Year Baseline Consumer Price Index [2022 September Vintage/Release]. Annual percent change

QUESTION NO. 33
Please refer to the Company's RMA 29 from the October 16, 2023 Traditional Test Year Compliance filing. Please explain why the Company proposes a 5-year amortization for the COVID-19 regulatory asset.

RESPONSE:

The Commission has approved various regulatory asset amortization periods in the past including 3, 5, and 15 years. Given prior Commission approvals for 5-year amortization of regulatory assets of similar size, including DLC Program Costs and the AMI True-up, the Company is proposing a 5-year amortization for the COVID-19 regulatory asset in this proceeding.

QUESTION NO. 39
Please refer to attachment PEPCO (K)-6 which includes the Energy Efficiency Calculations and Inputs. Please answer the following questions.

a. Please provide a program description for each of the included energy efficiency programs.

b. Please update PEPCO (K)-6 to include any actual data through June 2023.

c. Please provide the most recent program evaluation for each of the programs listed in PEPCO (K)-6.

d. Please describe the Company's process for forecasting the energy efficiency savings for programs that do not show any actual savings (or savings before 2023).

e. Please describe the Company's process for forecasting the energy efficiency savings for the behavior based program.

f. Please provide any analysis or studies that support the forecasted energy efficiency savings.

RESPONSE:

a. Program descriptions for each of the included energy efficiency programs in Pepco (K)-6 are provided below:

DC Sustainable Energy Utility: combination of energy efficiency programs administered by the DCSEU.

Efficient Products (Company-run program): provides incentives to increase the market share of Energy Star certified appliances such as clothes washers, dryers, refrigerators, room AC's, dehumidifiers, and heat pump water heaters.

Quick Home Energy Check Up (QHEC) (Company-run program): Energy auditor comes to the home and diagnosis ways for a customer to save energy at no cost. Also provides a number of energy efficient measures such as smart strips at no additional cost.

LMI Home Retrofit (Company-run program): Provides energy audits, rebates for efficient products, as well whole home upgrades directed at limited and moderate income customers. Whole home upgrades would be targeted at residential buildings serving 4 units or less.

Behavior Based (Company-run program): Leverages Pepco's investment in AMI, by providing personalized energy savings tips as well as similar homes comparison to nudge more efficient use of one's energy.

Merger - MF whole building RCx (Company-run program): Pepco's Income Eligible Multifamily Program which provides qualifying properties an energy assessment and energy-saving products installed throughout common areas and residents' units. This program was authorized through FC1148.

Small Business Program (Company-run program): provides incentives for retrofits for commercial customers with less than 100kW demand.

Existing Buildings (Company-run program): provides incentives and technical assistance to commercial customers in buildings less than 50,000 sq ft.

Midstream (Company-run program): Aides customers who purchase efficient equipment directly from distributor or manufacturer by offering instant rebates.

Commercial Behavior (Company-run program): Provides a Customer Engagement Portal to learn more about a customer's Individual energy use, tips for savings, and information on EE programs.

b. Please see FC1176 OPC DR 13-39 Attachment Confidential Electronic Only for actual data through June 2023.

c. Evaluations for the Company run programs listed in Pepco (K)-6 are not available as Pepco administered programs through FC1160 have yet to be approved and commence. For DC Sustainable Energy Utility please refer to the DCSEU for any evaluations done on their behalf.

d. Savings forecasts for energy efficiency programs that had no actual savings prior 2023 were based off the forecasted savings that were presented in Pepco's FC1160 filing. The Company only included savings from programs that were initially approved with modifications by the Commission in Order 21417.

e. The Company's forecast for the behavior-based program was taken from its FC1160 filing. The FC1160 forecast was derived from previously evaluated savings of the behavior-based programs the Company administers in nearby Maryland jurisdictions rescaled to the District's population.

f. Please see Pepco's Application, filed August 2, 2021 in FC1160, Appendix D, pg. 113 which serves as the basis for forecasted energy efficiency savings.

SPONSOR: Ekaterina Efimova and Morlon D. Bell-Izzard

POTOMAC ELECTRIC POWER COMPANY
DISTRICT OF COLUMBIA FORMAL CASE NO. 1176
RESPONSE TO OPC DATA REQUEST NO. 14

QUESTION NO. 4
Please refer to the Sale of Electricity line on Exhibit PEPCO (2B)-1. Please explain why the Company has not annualized these revenues for customer growth during the Historic Test Year.

RESPONSE:

As explained in Company Witness Leming's Supplemental Direct Testimony, the test period for the Company's traditional test year compliance filing is the 12 months ending December 31, 2023, with six months of actual data as of June 30, 2023 and six months of projected data from July through December 2023. The Sale of Electricity line item in Exhibit PEPCO (2B)-1 appropriately reflects the Company's revenues for this test period. Calculating test year base distribution revenues based on year-end customer counts would improperly over- or under-state the revenues for each rate class that the Company is allowed during the test year and would be inconsistent with prior traditional test year rate cases.

I. INTRODUCTION

Q PLEASE STATE YOUR NAME AND BUSINESS ADDRESS.

A My name is Christopher C. Walters. My business address is 16690 Swingley Ridge Road, Suite 140, Chesterfield, Missouri 63017.

Q WHAT IS YOUR OCCUPATION?

A I am a consultant in the field of public utility regulation and a Principal of Brubaker & Associates, Inc., energy, economic and regulatory consultants.

Q PLEASE DESCRIBE YOUR EDUCATIONAL BACKGROUND AND RELEVANT EMPLOYMENT EXPERIENCE.

A This information is included in Exhibit OPC (C)-1.

Q ON WHOSE BEHALF ARE YOU APPEARING IN THIS PROCEEDING?

A I am appearing in this proceeding on behalf of the Office of the People's Counsel for the District of Columbia ("OPC").

II. SUMMARY

Q WHAT IS THE SUBJECT MATTER OF YOUR TESTIMONY?

A My testimony will address the current market cost of equity, and resulting overall rate of return, for Potomac Electric Power Company ("Pepco" or the "Company"). My silence in regard to any issue should not be construed as an endorsement of Pepco's position

Q PLEASE SUMMARIZE YOUR RECOMMENDATIONS AND CONCLUSIONS.

A In Section III of my testimony, I review and analyze the regulated utility industry's access to capital, credit rating trends and outlooks, as well as the overall trend in the authorized Return on Equity ("ROE") for utilities throughout the country. I conclude that the trend in authorized ROEs for utilities has declined over the last several years and has remained below 10.0% more recently. I also review the impact that the Federal Reserve's (the "Fed") monetary policy actions have had on the cost of capital.

In Section IV of my testimony, I outline how a fair ROE should be established, provide an overview of the market's perception of the Company's investment risk, comment on the Company's proposed capital structure, and present the analyses I relied on to estimate an appropriate ROE for Pepco. Based on the results of several cost of equity estimation methods performed on publicly traded utility companies, I estimate the current fair market ROE for the Company to fall within the range of 9.20% to 9.90%, with a midpoint of 9.55%. This would be my recommendation under a traditional test year scenario without the BSA decoupling mechanism. Should the Commission allow Pepco to continue under a MYRP with, or without, the BSA, I would urge the Commission to adopt an ROE in the lower half of my recommended range of 9.20% to 9.55%, with a point estimate of 9.35%. This point estimate is 20 basis points below the midpoint of my recommended range and is consistent with the findings of this Commission's Order and Opinion in Formal Case No. 1156.[1]

In Section V of my testimony, I respond to the Company's witness Mr. McKenzie' estimate of the current market cost of equity for Pepco. Mr. McKenzie

---

[1] In its Order and Opinion issued in Formal Case No. 1156, the Commission noted that "Also, we find that Pepco would be benefiting from the combined risk-reducing effects of the BSA and the EMRP, which further supports our recommended ROE range with a midpoint that is 25 basis points below the currently approved ROE of 9.525%.", Order No. 20755, pg. 98, para. 243.

recommends the Company be authorized an ROE of 10.40% at the Company's proposed common equity ratio of 50.50%. I demonstrate that his recommendations are excessive and should be rejected.

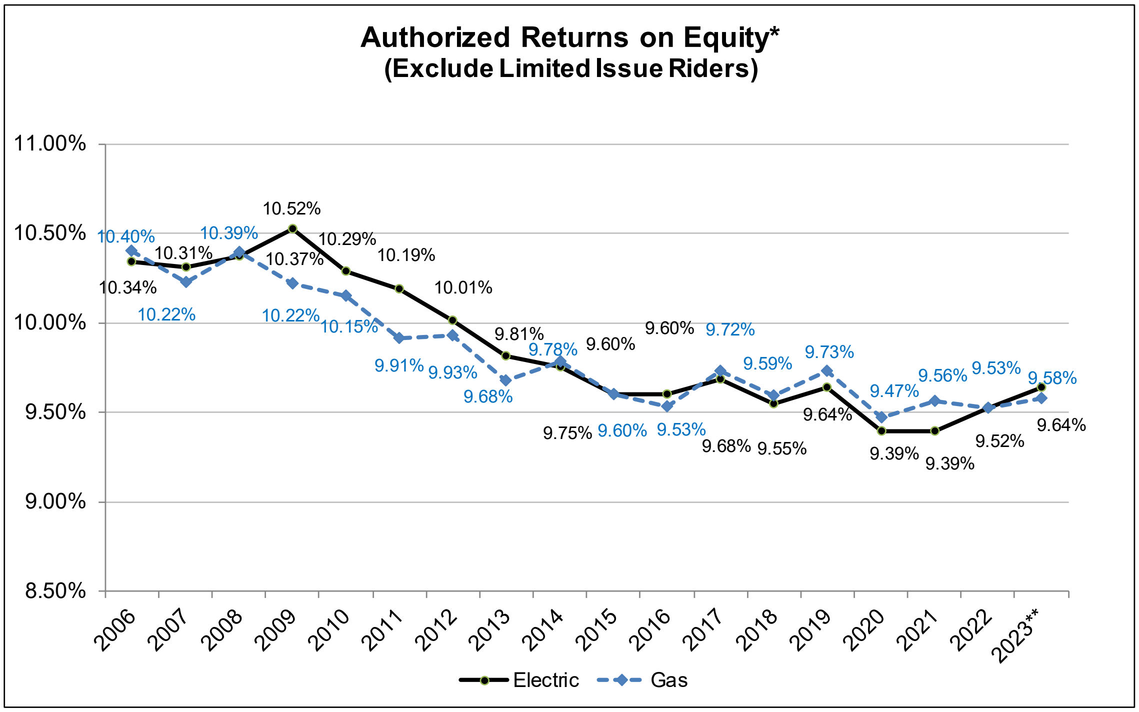
III. ACCESS TO CAPITAL AND ECONOMIC ENVIRONMENT

A. Regulated Utility Industry Authorized ROEs, Access to Capital, and Credit Strength

Q PLEASE DESCRIBE THE OBSERVABLE EVIDENCE ON TRENDS IN AUTHORIZED ROES FOR ELECTRIC AND GAS UTILITIES.

A Authorized ROEs for both electric and gas utilities have declined over the last ten years, as illustrated in Figure CCW-1, and have been below 10.0% for about the last ten years.

FIGURE CCW-1



Source and Notes:
* ROEs exclude Limited Issue Riders.
** *S&P Global Market Intelligence*, RRA Regulatory Focus, Major Rate Case Decisions -- January - June 2023, July 31, 2023 at page 4.

Q PLEASE DESCRIBE THE DISTRIBUTION OF AUTHORIZED ROES FOR ELECTRIC UTILITIES OVER THE LAST FEW YEARS.

A The distribution of authorized returns, annually, since 2016 is summarized in Table CCW-1.

TABLE CCW-1

Distribution of Authorized ROEs
(All Electric Utilities)*

Line	Year (1)	Average (2)	Median (3)	Share of Decisions ≤ 9.5%	Share of Decisions ≤ 9.7%	Share of Decisions ≤ 10.0%

S&P Global Market Intelligence, data through October 13, 2023.
[1]Includes authorized base ROE of 9.4% for Nevada Power Company, which excludes incentives associated with the Lenzie facility.
[2]Includes authorized base ROE of 9.6% for Interstate Power & Light Co., which excludes allowed ROE for generating facilities subject to special ratemaking principles.
[3]Includes authorized base ROE of 9.8% for Interstate Power & Light Co., which excludes allowed ROE for generating facilities subject to special ratemaking principles.
*Excludes Limited Issue Rider Cases.

The distribution shows that over the last few years, the majority of authorized ROEs since 2016 have been below 9.7%, with many of those being below 9.5%.

Q HOW HAS THE AUTHORIZED COMMON EQUITY RATIO FLUCTUATED OVER THE SAME TIME PERIOD FOR UTILITIES?

A In general, the utility industry's common equity ratio has not really deviated too much from the range of 50.0% to 52.0%. As shown in Table CCW-2 below, I have provided the authorized common equity ratios for utilities around the country, excluding the reported common equity ratios for Arkansas, Florida, Indiana and Michigan because these jurisdictions include sources of capital outside of investor-supplied capital such as accumulated deferred income taxes. As such, the reported common equity ratios in these states would result in a downward bias in the reported permanent common equity ratios authorized for ratemaking purposes within my trend analysis.

TABLE CCW-2

Trends in State Authorized Common Equity Ratios
(Industry)

Line	Year	Electric[1] Average	Electric[1] Median
	(1)	(2)	(3)
1	2016	49.70%	49.99%
2	2017	50.02%	49.85%
3	2018	50.60%	50.23%
4	2019	51.55%	51.37%
5	2020	50.94%	51.17%
6	2021	51.01%	52.00%
7	2022	51.66%	51.92%
8	2023	51.68%	52.29%
9	Average	50.90%	51.10%
10	Median	50.98%	51.27%

[2] Excludes Arkansas, Florida, Indiana, and Michigan, because they include non-investor capital.

Q HAVE REGULATED UTILITY COMPANIES BEEN ABLE TO MAINTAIN RELATIVELY STRONG CREDIT RATINGS DURING PERIODS OF DECLINING AUTHORIZED ROES?

A Yes. As shown below in Table CCW-3, the credit ratings of the industry have improved since 2009. In 2009, approximately 53% of the industry was rated BBB+ or higher. Currently, 82% of the industry has a rating of BBB+ or higher.[2]

Q HAVE UTILITIES BEEN ABLE TO ACCESS EXTERNAL CAPITAL TO SUPPORT CAPITAL EXPENDITURE PROGRAMS?

A Yes. Regulatory Research Associates ("RRA"), a division of S&P Global Market Intelligence, published a financial focus document entitled "Seismic shift in capex plans reported by utilities for 2023 through 2025" on March 16, 2023. In the Capex Report, RRA made several relevant comments about the record levels of utility investments generally (underlining added):

- 2023 is anticipated to be a record year of utility industry capital investments, with the aggregated forecast for the 46 tracked energy utilities exceeding $171 billion in

[2] May not add due to rounding.

capex this year, according to the results of analysis by Regulatory Research Associates.

- 2023 forecast capital expenditures by the RRA-tracked energy utilities are expected to be the greatest spending magnitude of any year-to-date, with the anticipated aggregate capex rising more than 18% compared with the 2022 realized spending of $144 billion by these 46 tracked utilities.

- Capex in the years 2024 and 2025 is forecast to expand incrementally each year to $173.4 billion and $177.1 billion, respectively, on spending growth in electric transmission, distribution and generation assets, as well as in the renewables sector.

- The nation's electric, gas and water utilities are investing in infrastructure at record levels to upgrade aging transmission and distribution systems; build new gas, solar and wind generation; and implement new technologies, including those related to smart meter deployment, smart grid systems, cybersecurity measures, electric vehicles and battery storage. The considerable spending levels are expected to serve as the basis for solid profit expansion in the utility industry for the foreseeable future.

- Several catalysts are anticipated to impel elevated spending over the next several years, including replacement of aging infrastructure, state renewable portfolio standards, federal infrastructure investment plans and tax credits that incentivize conversion of the nation's power generation network to zero-carbon sources. The federal Inflation Reduction Act of 2022 is also expected to play a substantial role over the next decade.[3]

As shown in Figure CCW-2 below, capital expenditures for the regulated utilities have increased considerably from 2022 into 2023, and the forecasted capital expenditures remain elevated through the end of 2025.

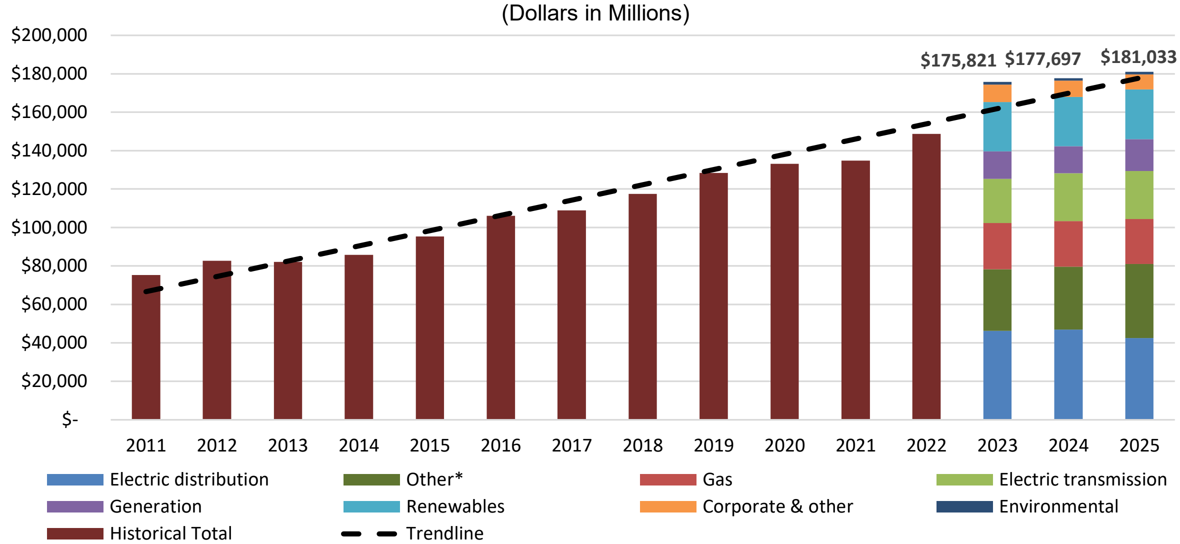
FIGURE 2

Utility Capital Expenditures
(Dollars in Millions)



*Other category consists of utilities that do not report capital expenditures by category: Avangrid, Hawaiian Electric, PG&E and Portland General Electric.
Source: *S&P Global Market Intelligence, RRA Financial Focus*, Utility Capital Expenditures Update, March 14, 2023, Tables 1 and 3.

As outlined in Figure CCW-2, and in the comments made in the Capex Report, capital investments for the utility industry continue to stay at elevated levels, and these capital expenditures are expected to fuel utilities' profit growth into the foreseeable future.

Q WHAT IS THE SIGNIFICANCE OF THESE FINDINGS?

A This is clear evidence that the capital investments are enhancing shareholder value and are attracting both equity and debt capital to the utility industry in a manner that allows for these elevated capital investments. While capital markets embrace these profit-driven capital investments, regulatory commissions also must be careful to maintain reasonable prices and tariff terms and conditions to protect customers' need for reliable utility service but at competitive and affordable tariff prices.

Q IS THERE EVIDENCE OF ROBUST VALUATIONS OF REGULATED UTILITY EQUITY SECURITIES?

A Yes. Robust valuations are an indication that utilities can sell securities at a premium, which is a strong indication that they can access equity capital under reasonable terms and conditions, and at relatively low cost. As shown on Exhibit OPC (C)-2, the historical valuation of utilities followed by *The Value Line Investment Survey* (*Value Line*)[4], based on a price-to-earnings (P/E) ratio, price-to-cash flow (P/CF) ratio, and market price-to-book value (M/B) ratio, indicates utility security valuations today are very strong and robust relative to the long-term average. These strong valuations of utility stocks indicate that utilities have access to equity capital under reasonable terms.

Q WHAT CONCLUSION DO YOU DRAW FROM THIS OBSERVABLE MARKET DATA INFORMING YOUR RECOMMENDED ROE AND OVERALL RATE OF RETURN?

A Generally, authorized ROEs, credit standing, and access to capital have been quite robust for utilities over the last several years, even throughout the duration of the global pandemic, elevated inflation, rising interest rates, and geopolitical events. It is critical that the Commission ensure that utility rates are increased no more than necessary to provide fair compensation and maintain financial integrity.

B. Federal Reserve Monetary Policy

Q ARE THE FEDERAL OPEN MARKET COMMITTEE'S ("FOMC") ACTIONS KNOWN TO THE MARKET PARTICIPANTS, AND IS IT REASONABLE TO BELIEVE THEY ARE REFLECTED IN THE MARKET'S VALUATION OF BOTH DEBT AND EQUITY SECURITIES?

A Yes to both questions. The Fed has been transparent about its efforts to support the economy to achieve maximum employment, and to manage long-term inflation to around a 2% level. The Fed has implemented procedures to support the economy's efforts to achieve these policy objectives. Specifically, the Fed had previously lowered the Federal Overnight Rate for securities and had engaged in a Quantitative Easing program where the Fed was buying, on a monthly basis, Treasury and mortgage-backed securities in order to moderate the demand in the marketplaces and support the economy. Currently, the Fed is unwinding its Quantitative Easing program and taking actions towards monetary policy normalization. Such monetary policy actions include raising the target federal funds rate and allowing bonds to mature and come off its balance sheet.

A visualization of the market's reaction to the Fed's actions on the federal funds rate is shown below Figure CCW-3.

FIGURE CCW-3

As shown in Figure CCW-3 above, the rise in the Federal Funds Rate has far outpaced the rise in Utility and Treasury yields while the spread of Utility bonds over Treasury bond yields have stabilized recently.

Q **HAS THE FED MADE RECENT COMMENTS CONCERNING MONETARY POLICY AND THE POTENTIAL IMPACT ON INTEREST RATES?**

A Yes. In its recent press release, the FOMC stated the following:

> Recent indicators suggest that economic activity has continued to expand at a modest pace. Job gains have been robust in recent months, and the unemployment rate has remained low. Inflation remains elevated. The U.S. banking system is sound and resilient. Tighter credit conditions for households and businesses are likely to weigh on economic activity, hiring, and inflation. The extent of these effects remains uncertain. The Committee remains highly attentive to inflation risks.
>
> The Committee seeks to achieve maximum employment and inflation at the rate of 2 percent over the longer run. In support of these goals, the Committee decided to maintain the target range for the federal funds rate at 5 to 5-1/4 percent. Holding the target range steady at this meeting allows the Committee to assess additional information and its implications for monetary policy. In determining the extent of additional policy firming that may be appropriate to return inflation to 2 percent over time, the Committee will take into account the cumulative tightening of monetary policy, the lags with which monetary policy affects economic activity and inflation, and economic and financial developments. In addition, the Committee will continue reducing its holdings of Treasury securities and agency debt and agency mortgage-backed securities, as described in its previously announced plans. The Committee is strongly committed to returning inflation to its 2 percent objective.
>
> In assessing the appropriate stance of monetary policy, the Committee will continue to monitor the implications of incoming information for the economic outlook. The Committee would be prepared to adjust the stance of monetary policy as appropriate if risks emerge that could impede the attainment of the Committee's goals. The Committee's assessments will take into account a wide range of information, including readings on labor market conditions, inflation pressures and inflation expectations, and financial and international developments.[5]

The above quotes suggest that the FOMC has recently shown signs of success in, and remains committed to, stabilizing consumer prices, and promoting maximum employment through its monetary policy tools.

Q WHAT DO INDEPENDENT ECONOMISTS' OUTLOOKS FOR FUTURE INTEREST RATES INDICATE?

A Independent economists, surveyed by *Blue Chip Financial Forecasts,* expect current capital costs to increase at mixed rates over the near term, while maintaining levels that are still low by historical standards. For example, independent projections show that the consensus is the federal funds rate will increase at a rate much faster than that of long-term interest rates as measured by the 30-year Treasury bond. Inflation, as measured through the Gross Domestic Product (GDP) price index, is expected to cool off in the near to intermediate term over the next six quarters.

The consensus projections for the next several quarters are provided in Table CCW-4 below.

*Average of all 3 reports in Quarter.

As outlined in Table CCW-5, the outlook for increases in interest rates has moderated since 2021. Indeed, interest rates are expected to remain flat, or even decline over the near and intermediate term. In fact, as shown on Figure CCW-3 above, increases in the federal funds rate do not necessarily translate into increases in longer-term yields.

C. Market Sentiments and Utility Industry Outlook

Q PLEASE DESCRIBE THE CREDIT RATING OUTLOOK FOR REGULATED UTILITIES.

A Credit analysts are concerned about rate affordability, driven by increases in commodity costs within rate base or capital investments, increases in interest rates, and credit analysts' concerns about utility rate affordability to customers. Each of these current outlooks for the credit standing of utility companies is discussed related to Standard & Poor's Ratings Service (S&P), Moody's Investors Service (Moody's), and Fitch Ratings (Fitch) perspectives. Specifically, S&P Global Ratings recently issued an "Industry Top Trends" report on North American Regulated Utilities which stated as follows:

> The industry outlook remains negative and has been negative since early 2020. Over this timeframe downgrades have outpaced upgrades by more than 3:1 [...]. While the industry's percentage of negative outlooks has decreased to about 15% from 35% at year-end 2020, prolonged inflationary risks or a deeper-than-expected recession could harm the industry's credit quality in 2023.[6]

At the time, the S&P Report noted that the industry outlook was negative; that the credit quality of the industry has changed to BBB+ from an A- rating over the last

---

6 S&P Global Ratings, "Industry Top Trends Update | North America: Regulated Utilities," January 23, 2023.

few years; that interest rates have increased for utilities; and that utilities have increased the use of securitization bonds for recovering storm, hurricane, and wildfire costs. S&P notes in the Report that key assumptions in its forecasted outlook for utilities include inflation outlooks (but expects inflation to decrease to around 4% by year-end 2023), continued robust capital spending for utilities (projecting over $190 billion expected to be spent in 2023), and increasing asset sales by utilities reflecting sales in minority interests in utilities and non-utility assets. S&P believes that the risks around its outlook include uncertainty about commodity prices, regulatory risks in responding to capital spending, other rate pressures on utilities to allow them to recover their cost of service, and physical risks to utility infrastructure from weather events and wildfires.

The credit analysts also use as a credit rating factor their concern regarding customers' ability to afford to pay their utility bills. S&P notes at page 4 the following related to the credit risks in 2023 and beyond:

> *Affordability of customer bill*
>
> Customer bills may become less affordable because of rising commodity prices, interest rates, inflation, and capital spending. During 2022, Henry Hub natural gas prices, the U.S. benchmark, peaked at about $9 per mmBTU. Although prices have since retreated to about $4/mmBTU and the forward curve reflects $3.50-$4.50/mmBTU, they remain substantially higher than preinflation levels, pressuring the customer bill. While we estimate the industry's average electric bill represents only about 2.5% of after-tax household income, sharp increases and bill volatility often results in increasing customer dissatisfaction that can ultimately heighten regulatory scrutiny and constrain the industry's ability to effectively manage regulatory risk.[7]

---

[7] *Id.*

Moody's had also changed the industry outlook to "Negative." Specifically, Moody's states:

> » **We have revised our outlook on the US regulated utilities sector to negative from stable.** We changed the outlook because of increasingly challenging business and financial conditions stemming from higher natural gas prices, inflation and rising interest rates. These developments raise residential customer affordability issues, increasing the level of uncertainty with regard to the timely recovery of costs for fuel and purchased power, as well as for rate cases more broadly.

> * * *
>
> » **What could change our outlook:** The outlook could return to stable if the sector's regulatory support remains intact, natural gas prices settle at a level where most utilities are able to fully recover fuel and purchased power costs without a delay beyond 12 months, overall inflation moderates, interest rates stabilize and/or the sector's aggregate (FFO)-to-debt ratio remains between 14% to 15%. We could change our outlook to positive if utility regulation turns broadly more credit supportive resulting in timelier cash flow recovery or we expect the sector's aggregate (FFO)-to-debt ratio to rise above 17% on a sustained basis.[8]

Fitch also revised its outlook for the utility sector due to the expectation for recession:

> Fitch Ratings sees high natural gas prices, record capital spending and rising interest rates among the cost pressures weighing on the U.S. utilities sector in 2023. The rating agency has a "deteriorating" outlook on the sector after years of a stable view.
>
> Other factors behind Fitch's outlook include the Edison Electric Institute predicting elevated levels of capital expenditures for U.S. electric utilities. EEI forecasts $154.7 billion of capital expenditures in 2022, $159.2 billion in 2023 and $155.2 billion in 2024, a sharp increase from $134.1 billion in 2021.

---

[8] *Moody's Investors Service Outlook*: "Regulated Electric and Gas Utilities – US; 2023 Outlook – Negative on higher natural gas prices, inflation and rising interest rates," November 10, 2022 at page 1 (emphasis added).

> Fitch is also mindful of how a "sharp escalation" in retail rates, which have increased 14% in 2022, and bill affordability will impact credit metrics. Higher natural gas prices are a key driver of this spike in retail rates.[9]

As outlined above, S&P, Moody's, and Fitch all state concern about utilities' rates affordability as a critical aspect of utility credit rating. Rate affordability largely should be considered by the Commission in ensuring that while certain aspects of utilities' cost of service are increasing, and must be reflected in the development of rates, other aspects such as fair rate of return including ROE and ratemaking capital structure may have discretionary elements which the Commission should consider in awarding an overall rate of return that is fair and reasonable to both the utility and, its investors, and is consistent with adjusting rates with a mind toward maintaining rate affordability to customers.

More recently, S&P has upgraded the outlook for regulated utilities from "negative" to "stable" due to improving economic conditions. Specifically, S&P notes:

> More recently, economic indicators have gradually improved. Inflation is increasing at a considerably slower pace with April's consumer price index (CPI) at 4.9% compared 9.1% in June 2022. Additionally, natural gas prices have significantly retreated from August 2022 highs when prices at Henry Hub approximated $9 per MMbtu. These healthier economic developments are consistent with S&P Global economists' forecast of CPI at about 4.7% by year-end 2023. This economic strengthening is also important for the utility industry. When gas prices peaked during 2022, many utilities deferred the recovery of these higher costs and are only now starting to bill ratepayers. The recent drop in natural gas prices provides some customer bill cushion, allowing the

---

[9] *S&P Capital IQPro*: "Fitch sees various cost pressures behind 'deteriorating' US utilities outlook at page 1, November 14, 2022 (emphasis added).

> utilities to bill customers for the previously deferred higher commodity costs without overwhelming the customer.[10]

In fact, in a July update, S&P further discussed the outlook for regulated utilities. Specifically, S&P notes:

> **Industry outlook.** In May we revised the industry's outlook to stable from negative, where it had been since early 2020. During the past three years, downgrades outpaced upgrades by more than 3:1 and the median industry rating fell to 'BBB+' from 'A-'. Over the next two years, we expect upgrades and downgrades will be more balanced.
>
> **Economic indicators are improving**. Over the past year, inflation increased at a slower rate and natural gas prices significantly retreated from 2022 highs of $9 per MMBtu, improving the industry's financial performance.
>
> **Credit-supportive tools reduce the impact of physical risks**. We don't expect the pace of hurricanes, wildfires, or storms to decline because of climate change. But we do expect system hardening, wildfire mitigation, higher storm reserves, self-insurance, and securitization will reduce much of the associated credit risks.[11]

D. Additional Remarks

Q PLEASE COMMENT ON RUSSIA'S INVASION OF UKRAINE AND ITS IMPACT ON THE MARKET.

A In late February 2022, Russia invaded Ukraine. The response from the United States and several other countries around the world has included several rounds of economic sanctions on Russia.

---

[10] S&P Global Ratings, *The Outlook For North American Regulated Utilities Turns Stable*, May 18, 2023, at page 7.

[11] S&P Global Ratings, "Industry Top Trends Update | North America: Regulated Utilities – Credit quality should stabilize", July 18, 2023.

While the actual and ongoing impact to the markets and global economy due to the current conflict remains to be seen, research on the markets during previous wars and armed combat situations provides an idea of what can be expected.

For example, a monograph published by the CFA Institute Research Foundation concluded as follows:

> Both wars and terrorist attacks tend to have only a transitory impact on financial markets, but clear exceptions test that tendency. The macroeconomic impact of wars tends to be significantly bigger in small economies and developing countries that cannot digest the negative effects of war as easily as large, open economies—such as that of the United States—can.[12]

While it is undeniable that a level of uncertainty exists because of the conflict in Ukraine, historical evidence indicates that the impact on financial markets is generally transitory.

Q IN LIGHT OF HIGHER LEVELS OF INFLATION, EXPECTATIONS OF HIGHER INTEREST RATES, AND THE WAR IN UKRAINE, HOW HAS THE MARKET PERCEIVED UTILITIES AS INVESTMENT OPTIONS?

A In 2023, the utility sector has underperformed the S&P 500. However, it should be noted that the performance of the S&P 500 is being driven by a handful of "mega cap" companies. Because the S&P 500 is a market capitalization weighted index (meaning the higher the market capitalization a company has, the more influence it has on the index's performance.) For example, in the S&P Dow Jones Indices report "U.S. Equity Market Attributes June 2023," it is noted that:

---

[12] Klement CFA, Joachim, CFA Institute Research Foundation, 2021, "Geo-Economics: The interplay of geopolitics, economics, and investments," 46 (emphasis added).

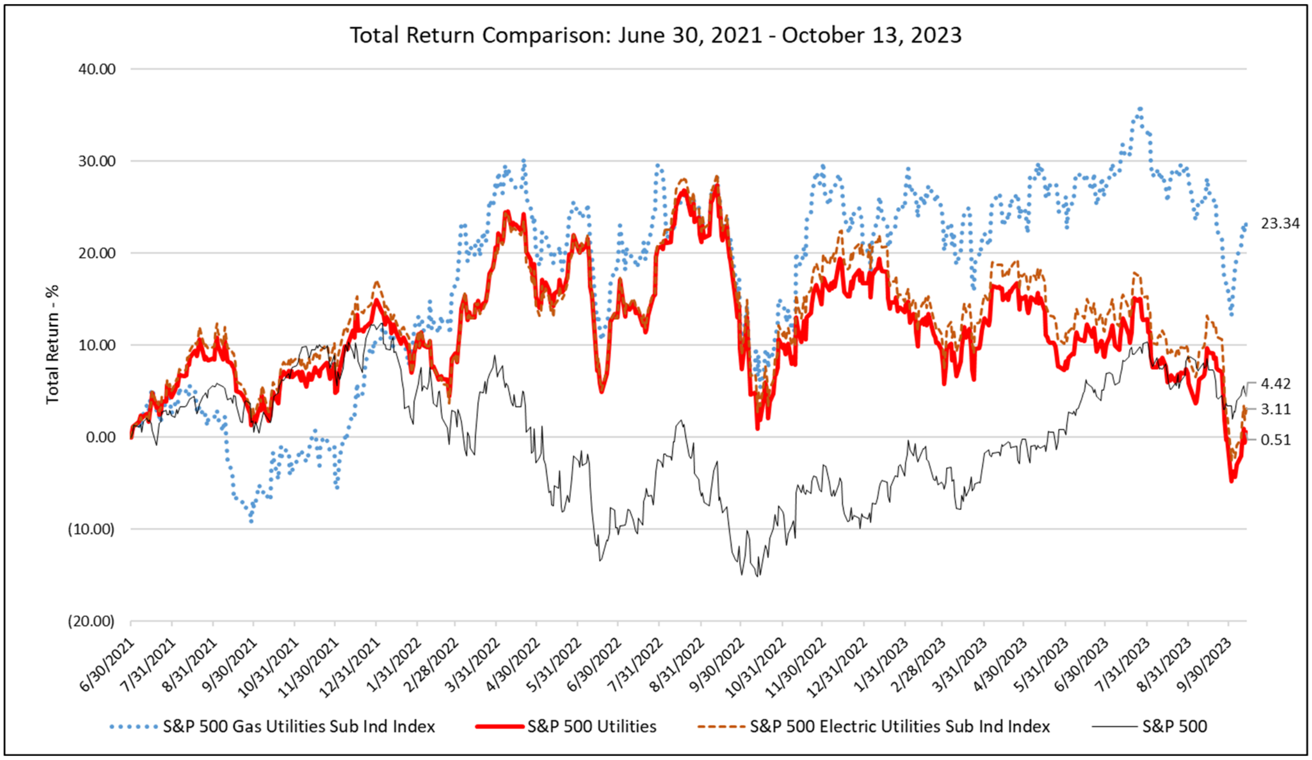
> For June, the S&P 500 total return was up 6.61%, with broad contributions across issues, compared to previous months when high-market-value issues dominated the market; underlying breadth (and contributions) remained negative. <u>That dominance still exists, as the index's total return was up 16.89% YTD, but without the top 44 issues, the index would be negative YTD, though that 44 was 8 in May.</u> Apple (AAPL) and Tesla (TSLA) were still on top for the month, with Alphabet (GOOG/L) (then Salesforce [CRM]) the largest negative contributor for the month.
>
> Meanwhile, the positive contributions were broad for June, even though they remain highly concentrated YTD. <u>The index is still top heavy, with the top 10 issues accounting for 30.5% of the market value (below 20% is more typical)</u>. Of note to the top of the market, semiconductor issue NVIDIA (NVDA) joined the USD 1 trillion in market value club this month, as Apple (which set a record at 7.72% of the index) became the first public issue to trade above USD 3 trillion in market value; the other three members of the club are Microsoft (MSFT), Alphabet and Amazon (AMZN).[13]

Notably, since the end of the second quarter 2021, utilities in general, as measured by the S&P 500 Utilities index as well as electric utilities specifically as measured by the S&P 500 Electric Utilities index, had largely performed on par with, or even outperformed the market as measured by the S&P 500. In early October, these indices experienced a significant decline due, in part, to the significant decline to the most valuable utility stock in the industry (as measured by market capitalization), NextEra Energy, which fell more than 25% in one week. Because S&P indices are value-weighted, meaning stocks with higher market capitalizations will have more weight in the index than lower market capitalization stocks, NextEra's major decline weighed heavily on the S&P utilities indices. This is presented below in Figure CCW-4. Notwithstanding that material decline, the graph below indicates that utility valuations

[13] https://www.spglobal.com/spdji/en/documents/commentary/market-attributes-us-equities-202306.pdf

remained robust, even during a period of elevated inflation, rising interest rates, and uncertainty because of geopolitical events around the world.

FIGURE CCW-4



IV. RETURN ON EQUITY

Q PLEASE DESCRIBE WHAT IS MEANT BY A "UTILITY'S COST OF COMMON EQUITY."

A A utility's cost of common equity is the expected return that investors require on an investment in the utility. Investors expect to earn their required return from receiving dividends and through stock price appreciation.

Q PLEASE DESCRIBE THE FRAMEWORK FOR DETERMINING A REGULATED UTILITY'S COST OF COMMON EQUITY.

A In general, determining a fair cost of common equity for a regulated utility has been framed by two hallmark decisions of the U.S. Supreme Court: Bluefield Water Works & Improvement Co. v. Pub. Serv. Comm'n of W. Va., 262 U.S. 679 (1923) and Fed. Power Comm'n v. Hope Natural Gas Co., 320 U.S. 591 (1944). In these decisions, the Supreme Court found that just compensation depends on many circumstances and must be determined by fair and enlightened judgments based on relevant facts. The Court also found that a utility is entitled to such rates as would permit it to earn a return on a property devoted to the convenience of the public that is generally consistent with the same returns available in other investments of corresponding risk. The Court continued that the utility has "no constitutional rights to profits" such as those "realized or anticipated in highly profitable enterprises or speculative ventures,"[14] and defined the ratepayer/investor balance as follows:

> The return should be reasonably sufficient to assure confidence in the financial soundness of the utility and should be adequate, under efficient and economical management, to maintain and support its credit and enable it to raise the money necessary for the proper discharge of its public duties.[15]

As such, a fair rate of return is based on the expectation that the utility costs reflect efficient and economical management, and the return will support its credit standing and access to capital, but the return will not be in excess of this level. Utility

---

[14] *Bluefield,* 262 U.S. at 692-93.
[15] *Ibid*. at 693 (emphasis added).

rates that are consistent with these standards will be just and reasonable, and compensation to the utility will be fair and support financial integrity and credit standing, under economic management of the utility.

Q PLEASE DESCRIBE THE METHODS YOU HAVE USED TO ESTIMATE PEPCO'S COST OF COMMON EQUITY.

A I have used several models based on financial theory to estimate Pepco's cost of common equity. These models are: (1) a constant growth Discounted Cash Flow ("DCF") model using consensus analysts' growth rate projections; (2) a constant growth DCF using sustainable growth rate estimates; (3) a multi-stage growth DCF model; (4) a Risk Premium model; and (5) a Capital Asset Pricing Model ("CAPM").

A. Pepco's Investment Risk

Q PLEASE DESCRIBE THE MARKET'S ASSESSMENT OF PEPCO'S INVESTMENT RISK.

A The market's assessment of a company's investment risk is generally described by credit rating analysts' reports. The current credit ratings for Pepco, from S&P and Moody's are A- and Baa1, respectively.[16] The Company currently has a "Stable" outlook from Moody's and a "Stable" outlook from S&P. S&P notes that its "stable" outlook on Pepco reflects its expectation that the Company's stand-alone financial measures will be consistent with the middle of the range for S&P's "significant" financial risk profile category, including funds from operations ("FFO") to debt of about 16%-18%.

Specifically, in its most recent report covering Pepco, S&P states:

[16] S&P Capital IQ, accessed on February 24, 2023.

Business Risk

Our assessment reflects the company's lower-risk, rate-regulated electric T&D operations. Pepco is a midsize utility providing services to more than 900,000 customers in Washington, D.C. and surrounding areas in Maryland. The company's residential customer base, which accounts for about 35% of its revenue, provides some cash flow stability and mitigates its exposure to the economic cyclicality that tends to be more pronounced with a higher proportion of industrial customers, which accounts for less than 50%.

Its distribution operations (about 80% of utility rate base) are regulated by the D.C. and Maryland PSCs, both of which have been somewhat challenging. The reliance on fully historical test periods in rate-setting contributes to regulatory lag and difficultly in earning authorized ROEs. With the implementation of the MRP in both jurisdictions, we expect reduced regulatory lag, enhanced rate predictability, and a greater opportunity for Pepco to earn its authorized ROE. In addition, further enhancing cash flow stability, Pepco utilizes a bill stabilization adjustment mechanism in both jurisdictions to mitigate the volatility of revenues and customer bills from weather and energy efficiency programs.

Financial Risk

Our base-case scenario that includes stand-alone FFO to debt in the 16%-18% range through 2024, the middle of the benchmark range for its financial risk profile category. We expect Pepco's leverage (current adjusted debt to EBITDA in the high-4x to low-5x range) to be aggressive through 2024. However, over the same period, we expect our supplemental ratio of adjusted FFO cash interest coverage will be in the 5x-5.5x range, bolstering our financial risk profile assessment. We expect Pepco's DCF to remain negative due to its dividends and robust capital spending, indicating external funding needs that we anticipate will include debt issuances. This necessitates that Pepco has consistent access to capital markets. We assess Pepco's financial risk profile using our medial volatility financial benchmarks, reflecting lower-risk regulated utility operations and effective management of regulatory risk. These benchmarks are more relaxed than those used for typical corporate issuers.[17]

[17] *S&P RatingsDirect®:* "Full Analysis: Potomac Electric Power Co.," December 8, 2022.

Q DO YOU BELIEVE THE PRESENCE OF AN MYRP REDUCES RISK TO SHAREHOLDERS?

A Yes, I do. There is substantial evidence to suggest that MYRPs are viewed as significant risk mitigating mechanisms to utility shareholders. For example, S&P had the following to say with regard to Ameren Illinois, which is a gas and wires-only electric utility operations:

> Legislation enacted in 2021 extends the FRP framework through 2023. Thereafter, companies can opt to file traditional base rate proceedings or a multiyear rate plan that would apply over a four-year period, each based on future test periods. Earlier this year, Ameren Illinois filed for a roughly $450 million total increase over a four-year period (2024-2027) to its electric distribution rates. <u>We believe either option is credit supportive because the use of a future test period minimizes regulatory lag. However, the four-year rate plan offers added predictability of rate recovery, which lowers uncertainty for the utility company and its stakeholders and promotes regulatory stability, which reduces business risk.</u>[18]

Further, RRA (a group within S&P Capital IQ) raised its assessment of North Carolina's regulatory climate upon enactment of the legislation allowing MYRPs, writing:

> On Oct. 13, 2021, RRA raised its ranking of North Carolina to Above Average/3 from Average/1 following the signing into law of comprehensive energy legislation that provides utilities the ability to file multiyear rate plans with the commission and develop performance-based incentives, with the ability to pursue regulatory approval for increases of up to 4% over three years rather than initiating a new rate case each year. The bill also effectively solidifies North Carolina's regulated energy monopoly system, maintaining the vertically integrated public utility model and commission regulatory authority. In doing so, it shuts down, at least for now, any hopes the state might move to an unregulated/competitive power market structure. The bill (House Bill

[18] *S&P RatingsDirect®:* "Full Analysis: Ameren Illinois Co.", March 23, 2023. (emphasis added).

> 951) also provides securitization as an option to recover costs associated with retiring coal plants.[19]

Further, this Commission has recognized as much as well in its Order and Opinion in Pepco's previous MYRP proceeding stating as follows:

> Based on the record, the Commission rejects Pepco's Original MRP and determines that Pepco's EMRP with modifications that we adopt, meets the statutory requirements for approval and will result in just and reasonable rates. The Commission, therefore, approves Pepco's EMRP, as modified (Modified EMRP) to include overarching terms as follows:
>
> a. A cumulative revenue requirement of $108.6 million representing a 33% reduction in revenue requirements from Pepco's original $162.0 million MRP proposal;
>
> b. <u>An authorized ROE of 9.275% and overall ROR of 7.17% to recognize the reduction in financial risk and regulatory lag</u>[20]

Q WHAT IS YOUR SUMMARY OF PEPCO'S INVESTMENT RISK?

A Pepco has strong credit ratings from S&P and Moody's. This is a result of its lower risk utility operations that benefit from constructive credit supportive mechanisms such as a MYRP and the BSA.

B. Pepco's Proposed Capital Structure

Q WHAT IS PEPCO'S PROPOSED CAPITAL STRUCTURE?

A Pepco's proposed capital structure is summarized in Table CCW-6 below:

---

19 *See, e.g., S&P Capital IQ:* "Duke Energy Carolinas files 1st NC multiyear rate request, seeking $833M," January 20, 2023.

20 Public Service Commission of The District Of Columbia, Formal Case No. 1156, Order and Opinion at para. 142. (emphasis added).

TABLE CCW-6

Investor-Supplied Capital Structure

Description	Weight
Long-Term Debt	49.50%
Common Equity	50.50%
Total	100.00%

Q **DO YOU HAVE ANY COMMENTS ON PEPCO'S PROPOSED CAPITAL STRUCTURE?**

A Yes. As I will discuss later, Pepco's proposed equity ratio of 50.50% significantly exceeds the equity ratio for the proxy group used to estimate the cost of equity for Pepco. As shown on Exhibit OPC (C)-3, the proxy group has an average common equity ratio of 39.0% (including short-term debt) and 42.9% (excluding short-term debt). The differences in financial risk need to be considered in the cost of equity estimation.

Q **ARE YOU AWARE OF OTHER REGULATORY COMMISSIONS RECOGNIZING THE NEED TO ALIGN THE COST OF EQUITY WITH THE CAPITAL STRUCTURE?**

A Yes. In a recent Order, the Arkansas Public Service Commission imputed the capital structure of Southwestern Electric Power Company ("SWEPCO") to be more in-line with the comparable companies used to estimate the cost of equity.[21] The adjustment

[21] APSC Docket No. 21-170-U, Doc. No. 323, May 23, 2022, Order No. 14.

was to recognize that there must be *congruence* between the cost of equity and the capital structure. Specifically, the Order states as follows:

> Consistent with our ruling in Order No. 10 of Docket No. 06-101-U, the Commission holds that there should be congruence between the estimated cost of equity and the [debt-to-equity "DTE")] ratio, whereby a lower DTE ratio decreases financial risk and decreases the cost of equity. The evidence of record supports imputing the average capital structure of companies with comparable risk to SWEPCO for the purposes of determining SWEPCO's overall cost of capital.[22]

As I described above, the proxy group has an average common equity ratio of 39.0% (including short-term debt) and 42.9% (excluding short-term debt) as calculated by S&P Global Market Intelligence and *Value Line*, respectively. The Company's proposed equity ratio of 50.50% (excluding short-term debt) is nearly 11 percentage points higher than that of the proxy group's comparable equity ratio. Clearly, Pepco's requested equity ratio exceeds the equity ratios of the proxy group used to assess the Company's cost of equity.

Q WHAT ARE YOUR CONCLUSIONS AS IT RELATES TO PEPCO'S PROPOSED CAPITAL STRUCTURE?

A As I explain above, the Company's proposed equity ratio of 50.50% (excluding short-term debt) significantly exceeds the equity ratios of the proxy group. While I am not making an adjustment to the capital structure, the differences in financial risk are taken into consideration of my overall recommendation.

---

[22] *Ibid*. at 25.

C. Development of Proxy Group

Q PLEASE BRIEFLY DESCRIBE WHY A PROXY GROUP IS NEEDED IN ESTIMATING THE COST OF EQUITY.

A There are a few reasons why a proxy group is needed to estimate the cost of equity. As an initial matter, to be consistent with the *Hope* and *Bluefield* standards, as described above, the allowed return should be commensurate with returns on investments in other firms of comparable risk. A proxy group of similarly situated companies of comparable risk is needed to assess the Company's proposal under this standard.

Even if Pepco were a publicly traded company whose securities could be used to estimate its cost of equity, there exists the potential for certain errors and biases making the reliance on a single estimate undesirable and potentially less accurate. A proxy group of comparable risk companies adds reliability to the estimates by mitigating the potential for bias that may be introduced by measurement errors of model inputs.

Q PLEASE DESCRIBE HOW YOU IDENTIFIED A PROXY UTILITY GROUP THAT COULD BE USED TO ESTIMATE PEPCO'S CURRENT MARKET COST OF EQUITY.

A I relied on the same proxy group developed by Pepco witness Mr. McKenzie.

Q HOW DOES THE INVESTMENT RISK OF PEPCO COMPARE TO THAT OF THE PROXY GROUP?

A As shown on my Exhibit OPC (C)-3, the proxy group has average credit ratings of BBB+ and Baa2 from S&P and Moody's, respectively. The proxy group's average rating of BBB+ from S&P is one notch lower than Pepco's A- rating from S&P, as well as the Company's Stand Alone Credit Profile ("SACP") rating of 'a-' from S&P. The proxy group's average rating of Baa2 from Moody's is also one notch lower than Pepco's rating of Baa1.

As shown on the same exhibit, the proxy group has an average common equity ratio of 39.0% (including short-term debt) and 42.9% (excluding short-term debt) as calculated by S&P Global Market Intelligence and *Value Line*, respectively. Pepco's requested common equity ratio of 50.50% (excluding short-term debt) significantly exceeds the proxy group's equity ratio as described above.

The differences in financial risk as measured by book value capital structures as well as the differences in credit ratings are indicative that the Company is of lower risk than the proxy group in general. This supports the premise that an ROE in the lower half of my recommended range is necessary should the Commission continue to allow Pepco to continue under a MYRP with, or without, the BSA.

D. DCF Model

Q PLEASE DESCRIBE THE DCF MODEL.

A The DCF model posits that a stock price equals the sum of the present value of expected future cash flows discounted at the investor's required rate of return or cost of capital. This model is expressed mathematically as follows:

$$P_0 = \frac{D_1}{(1+K)^1} + \frac{D_2}{(1+K)^2} \; .\;.\;.\;. \; \frac{D_\infty}{(1+K)^\infty} \qquad \text{(Equation 1)}$$

P_0 = Current stock price
D = Dividends in periods 1 - ∞
K = Investor's required return

This model can be rearranged in order to estimate the discount rate or investor-required return, known as "K." If it is reasonable to assume that earnings and dividends will grow at a constant rate, then Equation 1 can be rearranged as follows:

$$K = D_1/P_0 + G \qquad \text{(Equation 2)}$$

K = Investor's required return
D_1 = Dividend in first year
P_0 = Current stock price
G = Expected constant dividend growth rate

Equation 2 is referred to as the annual "constant growth" DCF model.

Q PLEASE DESCRIBE THE INPUTS TO YOUR CONSTANT GROWTH DCF MODEL.

A As shown in Equation 2 above, the DCF model requires a current stock price, the expected dividend, and the expected growth rate in dividends.

Q WHAT STOCK PRICE HAVE YOU RELIED ON IN YOUR CONSTANT GROWTH DCF MODEL?

A I relied on the average of the weekly high and low stock prices of the utilities in the proxy group over a 13-week period ending on October 13, 2023. An average stock price is less susceptible to market price variations than a price at a single point in time. Therefore, an average stock price is less susceptible to aberrant market price movements, which may not reflect the stock's long-term value. Similarly, it is not ideal to use a very long period of historical prices such that the average price reflects stale and/or information that is no longer relevant to the stock's valuation.

Q WHAT DIVIDEND DID YOU USE IN YOUR CONSTANT GROWTH DCF MODEL?

A I used each proxy company's most recently paid quarterly dividend as reported in *Value Line*.[23] This dividend was annualized (multiplied by 4) and adjusted for next year's growth to produce the D_1 factor for use in Equation 2 above. In other words, I calculate D_1 by multiplying the annualized dividend (D_0) by (1+G).

Q WHAT DIVIDEND GROWTH RATES HAVE YOU USED IN YOUR CONSTANT GROWTH DCF MODEL?

A There are several methods that can be used to estimate the expected growth in dividends. However, regardless of the method, for purposes of determining the market-required return on common equity, one must attempt to estimate investors' expectations about what the dividend, or earnings growth rate will be and not what an individual investor or analyst may use to make individual investment decisions.

As predictors of future returns, securities analysts' growth estimates have been shown to be more accurate than growth rates derived from historical data.[24] That is, assuming the market generally makes rational investment decisions, analysts' growth projections are more likely to influence investors' decisions, which are captured in observable stock prices, than growth rates derived only from historical data.

For my constant growth DCF analysis, I have relied on a consensus, or mean, of professional securities analysts' earnings growth estimates as a proxy for investors'

---

[23] *The Value Line Investment Survey*.

[24] *See*, e.g., David Gordon, Myron Gordon, and Lawrence Gould, Choice Among Methods of Estimating Share Yield, The Journal of Portfolio Management, Spring 1989.

dividend growth rate expectations for each of the proxy group companies. I used the average of analysts' growth rate estimates from three sources: Zacks, S&P Capital IQ Market Intelligence ("MI"), and Yahoo! Finance. All such projections were available on October 13, 2023, and all were reported online.[25]

Each growth rate projection is based on a survey of independent securities analysts. There is no clear evidence whether a particular analyst is most influential on general market investors. Therefore, a single analyst's projection does not predict investor outlooks as reliably as does a consensus of market analysts' projections. The consensus of estimates is a simple arithmetic average, or mean, of surveyed analysts' earnings growth forecasts. A simple average of the growth forecasts gives equal weight to all surveyed analysts' projections. Therefore, a simple average, or arithmetic mean, of analysts' forecasts is a good proxy for investor expectations.

The growth rates I used in my DCF analysis are shown in Exhibit OPC (C)-4. The average growth rate for my proxy group is 6.16% and a median growth rate of 6.21%.

---

[25] www.zacks.com; https://finance.yahoo.com; and https://www.capitaliq.spglobal.com/.

Q WHAT ARE THE RESULTS OF YOUR CONSTANT GROWTH DCF MODEL?

A As shown in Exhibit OPC (C)-5, page 1, the average and median constant growth DCF returns for my proxy group for the 13-week analysis are 10.24% and 10.21%, respectively.

Q DO YOU HAVE ANY COMMENTS ON THE RESULTS OF YOUR CONSTANT GROWTH DCF ANALYSIS?

A Yes. The constant growth DCF analysis for my proxy group is based on a group average long-term growth rate of 6.16%. The three- to five-year growth rates are approximately 36% higher than the long-term projected GDP growth rate of 4.04%, described below. As I explain in detail below, a utility's growth rate cannot exceed the growth rate of the economy in which it provides services in perpetuity, which is the time period assumed by the DCF model.

Q HOW DID YOU IDENTIFY THE LONG-TERM PROJECTED GDP GROWTH RATE?

A Although there may be short-term peaks, the long-term sustainable growth rate for a utility stock cannot exceed the growth rate of the economy in which it sells its goods and services. The long-term maximum sustainable growth rate for a utility investment is limited by the projected long-term GDP growth rate as that reflects the projected long-term growth rate of the economy as a whole. *Blue Chip Economic Indicators* projects that over the next 5 and 10 years, the U.S. nominal GDP will grow at an annual rate of approximately 4.04%.[26] As such, the average nominal growth rate over the next 10 years is around 4.04%, which I believe is a reasonable proxy of long-term growth.

Later in this testimony, I discuss academic and investment practitioner support for using the projected long-term GDP growth outlook as a maximum long-term growth rate projection. Using the long-term GDP growth rate as a conservative projection for the maximum growth rate is logical, and is generally consistent with academic and economic practitioner accepted practices.

E. Sustainable Growth DCF

Q PLEASE DESCRIBE WHAT THE SUSTAINABLE GROWTH DCF METHOD IS AND HOW YOU ESTIMATED A SUSTAINABLE GROWTH RATE FOR YOUR SUSTAINABLE GROWTH DCF MODEL.

A The sustainable growth rate, also referred to as the internal growth rate, is determined by the proportion of the utility's earnings that is retained and reinvested in its plant and equipment. These reinvested earnings enhance the earnings base, also known as the rate base. The earnings grow as the plant, funded by the reinvested earnings, is put into operation, allowing the utility to receive its authorized return on the additional rate base investment.

The internal growth approach is linked to the percentage of earnings retained within the company, as opposed to being paid out as dividends. The earnings retention ratio is calculated as 1 minus the dividend payout ratio. As the payout ratio decreases,

[26] Blue Chip Economic Indicators October 10, 2023, at page 14.

the retention ratio increases, leading to stronger growth as the company funds more investments using retained earnings.

The payout ratios of the proxy group are shown in my Exhibit OPC (C)-6. These dividend payout ratios and earnings retention ratios then can be used to develop a long-term growth rate driven by earnings retention.

The data used to estimate the long-term sustainable growth rate is based on the Company's current market-to-book ratio and on *Value Line*'s three- to five-year projections of earnings, dividends, earned returns on book equity, and stock issuances.

As shown in Exhibit OPC (C)-7, the average and median sustainable growth rates for the proxy group using this internal growth rate model are 4.89% and 5.08%, respectively.

Q WHAT IS THE DCF ESTIMATE USING THESE SUSTAINABLE GROWTH RATES?

A A DCF estimate based on these sustainable growth rates is developed in Exhibit OPC (C)-8. As shown there, and using the same formula in Equation 2 above, a sustainable growth DCF analysis produces proxy group average and median DCF results for the 13-week period of 8.93% and 8.88%, respectively.

F. Multi-Stage Growth DCF Model

Q HAVE YOU CONDUCTED ANY OTHER DCF STUDIES?

A Yes. As previously noted, the DCF model is intended to represent the present value of an endless series of future cash flows. Nevertheless, the initial constant growth DCF that I created is based on analyst growth rate projections, providing a plausible representation of rational investment expectations over the next three to five years. The limitation of this constant growth DCF model is that it cannot reflect a reasonable expectation of a shift in growth from a high or low short-term rate to a rate that aligns more with long-term sustainable growth. To accommodate changing growth expectations, I conducted a multi-stage DCF analysis that reflects growth rate change over time.

Q WHY DO YOU BELIEVE GROWTH RATES CAN CHANGE OVER TIME?

A The growth rate projections for the next three to five years by analysts are subject to change as the outlook for utility earnings growth evolves. Utility companies experience fluctuations in their investment cycles. When these companies are undertaking substantial investments, the growth of their rate base accelerates, leading to an increase in earnings growth. However, once a major construction cycle reaches completion or plateaus, the growth in the utility rate base slows down, and its earnings growth rate declines from an abnormally high three to five-year rate to a lower, sustainable growth rate.

As construction cycles become longer in duration, even with an aggressive construction plan, the growth rate of the utility will naturally slow due to a decrease in rate base growth, as the utility has limited human and capital resources to expand its construction activities. Therefore, the three to five-year growth rate projection should be viewed as a long-term sustainable growth rate, but not without considering the current market conditions, industry trends, and determining whether the three to five-year growth outlook is feasible and sustainable.

Q PLEASE DESCRIBE YOUR MULTI-STAGE DCF MODEL.

A The multi-stage DCF model reflects the possibility of non-constant growth for a company over time. The multi-stage DCF model reflects three growth periods: (1) a short-term growth period consisting of the first five years; (2) a transition period, consisting of the next five years (6 through 10); and (3) a long-term growth period starting in year 11 and extending into perpetuity.

For the short-term growth period, I relied on the consensus of analysts' growth projections described above in relationship to my constant growth DCF model. For the transition period, the growth rates were reduced or increased by an equal factor reflecting the difference between the analysts' growth rates and the long-term sustainable growth rate. For the long-term growth period, I assumed each company's growth would converge to the maximum sustainable long-term growth rate.

Q WHY IS THE GDP GROWTH PROJECTION A REASONABLE PROXY FOR THE MAXIMUM SUSTAINABLE LONG-TERM GROWTH RATE?

A Utilities cannot indefinitely sustain a growth rate that exceeds the growth rate of the economy in which they sell services. Utilities' earnings and dividend growth is created by increased utility investment in its rate base. Examples of what can drive such investment are service area economic growth, system reliability upgrades, or state and federal green energy initiatives. As a result, nominal GDP growth is a reasonable upper limit for utility sales growth, rate base growth, and earnings growth in the long-run. Therefore, the U.S. GDP nominal growth rate is a conservative proxy for the highest sustainable long-term growth rate of a utility.

Q IS THERE RESEARCH THAT SUPPORTS YOUR POSITION THAT, OVER THE LONG-TERM, A COMPANY'S EARNINGS AND DIVIDENDS CANNOT GROW AT A RATE GREATER THAN THE GROWTH OF THE U.S. GDP?

A Yes. This concept is supported in published analyst literature and academic work. Specifically, in a textbook titled "Fundamentals of Financial Management," published by Eugene Brigham and Joel F. Houston, the authors state as follows:

> The constant growth model is most appropriate for mature companies with a stable history of growth and stable future expectations. Expected growth rates vary somewhat among companies, but <u>dividends for mature firms are often expected to grow in the future at about the same rate as nominal gross domestic product (real GDP plus inflation)</u>.[27]

The use of the economic growth rate is also supported by investment practitioners as outlined as follows:

> **Estimating Growth Rates**
>
> One of the advantages of a three-stage discounted cash flow model is that it fits with life cycle theories in regards to company growth. In these theories, companies are assumed to have a life cycle with varying growth characteristics. Typically, the potential for extraordinary growth in the near term eases over time and eventually growth slows to a more stable level.
>
> * * *
>
> Another approach to estimating long-term growth rates is to focus on estimating the overall economic growth rate. Again, this is the approach used in the *Ibbotson Cost of Capital Yearbook*. To obtain the economic growth rate, a forecast is made of the growth rate's component parts. Expected growth can be broken into two main parts: expected inflation and expected real growth. By analyzing these components separately, it is easier to see the factors that drive growth.[28]

---

27 *Fundamentals of Financial Management*, Eugene F. Brigham and Joel F. Houston, Eleventh Edition 2007, Thomson South-Western, a Division of Thomson Corporation at 298 (emphasis added).

28 Morningstar, Inc., Ibbotson SBBI 2013 Valuation Yearbook at 51 and 52.

Q ARE YOU AWARE OF ANY RESEARCH THAT DEMONSTRATING THAT MULTI-STAGE DCF MODELS ARE USED IN THE INVESTMENT INDUSTRY?

A Yes. The CFA Institute curriculum text states as follows:

> Multistage models are a staple valuation discipline of investment management firms using DCF valuation models.
> A survey of CFA Institute members with job responsibility for equity analysis indicates that, among respondents using a dividend discount model, two-stage and multistage models are used more often than the single-stage model (Stowe, Pinto, and Robinson 2018). Among analysts using a dividend discount model, 55% use a two-stage model, 11% use an H-model (a type of two-stage model), and 50% use a model with more than two stages (Stowe, Pinto, and Robinson 2018).[29]

As Stowe *et al* have revealed, the majority of equity analysts rely on multi-stage models more frequently than single stage or constant growth models.

Q HOW DID YOU DETERMINE A LONG-TERM GROWTH RATE THAT REFLECTS THE CURRENT CONSENSUS OF INDEPENDENT MARKET PARTICIPANTS?

A I relied on the consensus of long-term GDP growth projections as projected by independent economists. *Blue Chip Financial Forecasts* publishes the consensus for GDP growth projections twice a year. These projections reflect current outlooks for GDP and are likely to be influential on investors' expectations of future growth outlooks. The consensus of projected GDP growth is about 4.04% over the next 10 years.[30]

---

[29] Chartered Financial Analyst Institute, 2023 CFA Program Level 2 Refresher Reading, Equity Valuation: Discounted Dividend Valuation, at 30. [footnote omitted].

[30] Blue Chip Economic Indicators October 10, 2023, at page 14.

Q DO YOU CONSIDER OTHER SOURCES OF PROJECTED LONG-TERM GDP GROWTH?

A Yes, and these alternative sources corroborate the consensus analysts' projections I relied on. Several projections are shown in Table CCW-7 below.

TABLE CCW-7

GDP Forecasts

Source	Projected Period	Real GDP	Inflation	Nominal GDP
Blue Chip Financial Forecasts [1]	5-10 Yrs	1.9%	2.2%	4.0%
EIA - Annual Energy Outlook[2]	27 Yrs	1.9%	2.3%	4.3%
Congressional Budget Office[3]	30 Yrs	1.6%	2.1%	3.7%
Moody's Analytics[4]	31 Yrs	2.0%	2.0%	4.0%
Social Security Administration[5]	77 Yrs	1.6%	2.4%	4.1%
Economist Intelligence Unit[6]	29 Yrs	1.7%	2.2%	3.9%

Sources:
[1]Blue Chip Financial Forecasts, October 10, 2023 at 14.
[2]U.S. EnergyInformation Administration (EIA), Annual Energy Outlook 2023, September, 2022.
[3]Congressional Budget Office, Long-Term Budget Outlook, July 2022.
[4]Moody's Analytics Forecast, downloaded January 17, 2023.
[5]Social Security Administration, "2023 OASDI Trustees Report," Table VI.G6. March 31, 2023.
[6]S&P MI, Economist Intelligence Unit, downloaded on April 5, 2023.

As shown in the table above, the real GDP and the inflation fall in the range of 1.6% to 2.1% and 2.0% to 2.4%, respectively. This results in a nominal GDP in the range of 3.7% to 4.3%, with an average of 4.1%. Therefore, the nominal GDP growth projections made by these independent sources support my use of 4.04% as a reasonable estimate of market participants' expectations for long-term GDP growth. The real GDP and nominal GDP growth projections made by these independent sources support my use of 4.04% as a reasonable estimate of market participants' expectations for long-term GDP growth.

Q WHAT STOCK PRICE, DIVIDEND, AND GROWTH RATES DID YOU USE IN YOUR MULTI-STAGE DCF ANALYSIS?

A I relied on the same 13-week average stock prices and the most recent quarterly dividend payment data discussed above. For the first stage, I used the consensus of analysts' growth rate projections discussed above in my constant growth DCF model. The first stage covers the first five years, consistent with the time horizon of the securities analysts' growth rate projections. The second stage, or transition stage, begins in year 6 and extends through year 10. The second stage growth transitions the growth rate from the first stage (consensus growth rate estimates) to the third stage (long-term GDP) using a straight linear trend. For the third stage, or long-term sustainable growth stage, starting in year 11, I used a 4.04% long-term sustainable growth rate based on the consensus of economists' long-term projected nominal GDP growth rate.

Q WHAT ARE THE RESULTS OF YOUR MULTI-STAGE DCF MODEL?

A As shown in Exhibit OPC (C)-9, the average and median DCF ROEs for my proxy group using the 13-week average stock price are 8.59% and 8.53%, respectively.

Q PLEASE SUMMARIZE THE RESULTS FROM YOUR DCF ANALYSES.

A The DCF results are summarized in Table CCW-8 below. As noted above, the much higher Constant Growth DCF Model (Analysts' Growth) result is based on a projected growth rate that far exceeds projected GDP growth, which is unsustainable in perpetuity. It is my opinion a reasonable ROE based on the DCF results summarized in Table CCW-8 is 9.20%.

TABLE CCW-8

Summary of DCF Results

Description	Proxy Group Average	Proxy Group Median
Constant Growth DCF Model (Analysts' Growth)	10.24%	10.21%
Constant Growth DCF Model (Sustainable Growth)	8.93%	8.88%
Multi-Stage DCF Model	8.59%	8.53%

G. Risk Premium Model

Q PLEASE DESCRIBE YOUR BOND YIELD PLUS RISK PREMIUM MODEL.

A This model is based on the principle that investors require a higher return to assume greater risk. Common equity investments have greater risk than bonds because bonds have more security of payment in bankruptcy proceedings than common equity and the coupon payments on bonds represent contractual obligations. In contrast, companies are not required to pay dividends or guarantee returns on common equity investments. Therefore, common equity securities are considered to be riskier than bond securities.

This risk premium model is based on two estimates of an equity risk premium. First, I quantify the difference between regulatory commission-authorized returns on common equity and contemporary U.S. Treasury bonds. The difference between the authorized return on common equity and the Treasury bond yield is the risk premium. I estimated the risk premium on an annual basis for each year since January 1986. The authorized ROEs were based on regulatory commission-authorized returns for utility companies. Authorized returns are typically based on expert witnesses' estimates of the investor-required return at the time of the proceeding.

The second equity risk premium estimate is based on the difference between regulatory commission-authorized returns on common equity and contemporary "A" rated utility bond yields by Moody's. I selected the period 1986 through the present because public utility stocks have consistently traded at a premium to book value during that period. This is illustrated in Exhibit OPC (C)-10, which shows the market-to-book ratio since 1986 for the utility industry was consistently above a multiple of 1.0x. Over this period, an analyst can infer that authorized ROEs were sufficient to support market prices that at least exceeded book value. This is an indication that commission-authorized returns on common equity supported a utility's ability to issue additional common stock without diluting existing shares. It further demonstrates that utilities were able to access equity markets without a detrimental impact on current shareholders.

Based on this analysis, as shown in Exhibit OPC (C)-11, the average indicated equity risk premium over U.S. Treasury bond yields has been 5.72%. Since the risk premium can vary depending upon market conditions and changing investor risk perceptions, I believe using an estimated range of risk premiums provides the best method to measure the current return on common equity for a risk premium methodology.

I assessed the five-year and ten-year rolling average risk premiums over the study period to gauge the variability over time of risk premiums. These rolling average risk premiums mitigate the impact of anomalous market conditions and skewed risk premiums over an entire business cycle. As shown on my Exhibit OPC (C)-11, the five-year rolling average risk premium over Treasury bonds ranged from 4.25% to 7.09%, while the ten-year rolling average risk premium ranged from 4.38% to 6.91%.

As shown on my Exhibit OPC (C)-12, the average indicated equity risk premium over contemporary "A" rated Moody's utility bond yields was 4.35%. The five-year and ten-year rolling average risk premiums ranged from 2.88% to 5.90% and 3.20% to 5.73%, respectively.

Q WHY ARE THE TIME PERIODS USED TO DERIVE THESE EQUITY RISK PREMIUM ESTIMATES APPROPRIATE TO FORM ACCURATE CONCLUSIONS ABOUT CONTEMPORARY MARKET CONDITIONS?

A Contemporary market conditions can change dramatically during the period that rates determined in this proceeding will be in effect. A relatively long period of time where stock valuations reflect premiums to book value indicates that the authorized ROEs and the corresponding equity risk premiums were supportive of investors' return expectations and provided utilities access to the equity markets under reasonable terms and conditions. Further, this time period is long enough to smooth abnormal market movement that might distort equity risk premiums. While market conditions and risk premiums do vary over time, this historical time period is a reasonable period to estimate contemporary risk premiums.

Q PLEASE EXPLAIN OTHER MARKET EVIDENCE YOU RELIED ON IN DETERMINING AN APPROPRIATE EQUITY RISK PREMIUM.

A The equity risk premium should reflect the market's perception of risk in the utility industry today. I have gauged investor perceptions in utility risk today in Exhibit OPC (C)-13, where I show the yield spread between utility bonds and Treasury bonds since 1980. As shown in this schedule, the average utility bond yield spreads over Treasury bonds for "A" and "Baa" rated utility bonds for this historical period are 1.49% and 1.91%, respectively.

A current 13-week average "A" rated utility bond yield of 5.81% when compared to the current Treasury bond yield of 4.39%, as shown in Exhibit OPC (C)-14, page 1, implies a yield spread of 1.42%. This current utility bond yield spread is identical to the long-term average spread for "A" rated utility bonds of 1.49%. The 13-week average yield on "Baa" rated utility bonds is 6.10%. This indicates a current spread for the "Baa" rated utility bond yield of 1.71%, which is slightly lower than the long-term average of 1.91%.

Q WHAT IS YOUR RECOMMENDED RETURN FOR THE COMPANY BASED ON YOUR RISK PREMIUM STUDY?

A Considering the current and projected economic environment, current yield spreads and equity risk premiums, as well as current levels of interest rates and interest rate projections, a more normalized equity risk premium is warranted. As such, I believe an average equity risk premium over Treasury yields of 5.72% is appropriate. Adding this risk premium to the projected Treasury yield of 4.00% produces an ROE of 9.72%.

Applying a similar methodology as described above, the average of the rolling five-year average risk premiums over A-rated utility bonds is 4.35%. The A-rated utility bond yield has averaged 5.81% over the 13-week period ending October 13, 2023 while the Baa-rated utility bond yield has averaged 6.10% over the same period. Adding this risk premium to the 13-week A-rated utility bond yield of 5.81% produces an estimated cost of equity of 10.16%. Adding this risk premium to the 13-week Baa-rated utility bond yield of 6.10% produces an estimated cost of equity of 10.45%.

The A-rated utility bond yield has averaged 5.58% over the 26-week period ending October 13, 2023 while the Baa-rated utility bond yield has averaged 5.90% over the same period. Adding this risk premium to the 26-week A-rated utility bond yield of 5.58% produces an estimated cost of equity of 9.93%. Adding this risk premium to the 26-week Baa-rated utility bond yield of 5.90% produces an estimated cost of equity of 10.25%.

The results of my risk premium analyses are summarized in Table CCW-9. Because the exercise of determining the cost of equity is forward looking, in my opinion, based on these results, my risk premium analyses yield a recommended ROE of 9.90%.

TABLE CCW-9

Summary of Risk Premium Results

Description	
Projected Treasury Yield	9.72%
13-Week Yields	
A-Rated Utility Bond	10.16%
Baa-Rated Utility Bond	10.45%
26-Week Yields	
A-Rated Utility Bond	9.93%
Baa-Rated Utility Bond	10.25%

Q HOW DO YOUR EQUITY RISK PREMIUMS COMPARE TO WHAT HAS BEEN REALIZED YEAR-TO-DATE?

A Year-to-Date, the equity risk premium over prevailing bond yields has been near long-term averages. As such, a more modest equity risk premium such as the long-term average or medians would be reasonable considerations at this time.

H. Capital Asset Pricing Model ("CAPM")

Q PLEASE DESCRIBE THE CAPM.

A The CAPM method of analysis is based upon the theory that the market-required rate of return for a security is equal to the risk-free rate, plus a risk premium associated with the specific security. This relationship between risk and return can be expressed mathematically as follows:

$R_i = R_f + B_i \times (R_m - R_f)$ where:

R_i = Required return for stock i
R_f = Risk-free rate
R_m = Expected return for the market portfolio
B_i = Beta - Measure of the risk for stock

The term "beta" in the equation represents the stock-specific risk that cannot be reduced through diversification. In a well-diversified portfolio, specific risks related to individual stocks can be reduced by balancing the portfolio with securities that offset the impact of firm-specific factors, such as business cycle, competition, product mix, and production limitations.

Non-diversifiable risks, on the other hand, are related to market conditions and are referred to as systematic risks. These risks cannot be reduced through diversification and are considered market risks. Conversely, non-systematic risks, also known as business risks, can be reduced through diversification.

According to the CAPM, the market does not compensate investors for taking on risks that can be diversified away. Thus, investors are only compensated for taking on systematic, or non-diversifiable, risks. Beta is a measure of these systematic risks.

Q PLEASE DESCRIBE THE INPUTS TO YOUR CAPM.

A The CAPM requires an estimate of the market risk-free rate, the company's beta, and the market risk premium.

Q WHAT DID YOU USE AS AN ESTIMATE OF THE MARKET RISK-FREE RATE?

A As previously noted, *Blue Chip Financial Forecasts*' projected 30-year Treasury bond yield is 4.00%.[31] The current 30-year Treasury bond yield is 4.39%, as shown in Exhibit OPC (C)-14 at page 1. I used *Blue Chip Financial Forecasts*' projected 30-year Treasury bond yield of 4.00% for my CAPM analysis.

Q WHY DID YOU USE LONG-TERM TREASURY BOND YIELDS AS AN ESTIMATE OF THE RISK-FREE RATE?

A Treasury securities are backed by the full faith and credit of the United States government, so long-term Treasury bonds are considered to have negligible credit risk. Also, long-term Treasury bonds have an investment horizon similar to that of common stock. As a result, investor-anticipated long-run inflation expectations are reflected in both common stock required returns and long-term bond yields. Therefore, the nominal risk-free rate (or expected inflation rate and real risk-free rate) included in a long-term bond yield is a reasonable estimate of the nominal risk-free rate included in common stock returns.

Treasury bond yields, however, do include risk premiums related to future inflation and liquidity. In this regard, a Treasury bond yield is not entirely risk-free. Risk premiums related to unanticipated inflation and interest rates reflect systematic market risks. Consequently, for a company with a beta less than 1.0, using the Treasury

---

[31] Blue Chip Financial Forecasts, October 2, 2023 at 2.

bond yield as a proxy for the risk-free rate in the CAPM analysis can produce an overstated estimate of the CAPM return.

Q WHAT BETA DID YOU USE IN YOUR ANALYSIS?

A As shown in Exhibit OPC (C)-15, the current proxy group average and median *Value Line* beta estimates are 0.92 and 0.90, respectively. In my experience, these beta estimates are abnormally high and are unlikely to be sustained over the long-term. Because these beta estimates are calculated using five years of historical prices, they reflect the market's fallout when the market lost more than 40% of its value in early 2020 as a result of the COVID-19 pandemic. As shown on Exhibit OPC (C)-15, page 2, utility stock betas were on a declining trend and at the lowest point since 2014 leading up to the pandemic. In other words, current *Value Line* betas are being heavily impacted by the onset of extreme market volatility and fear from a two-month period over February and March of 2020, and likely do not accurately represent current investor expectations. As such, I have also considered the historical average of the proxy group's *Value Line* betas. The historical average *Value Line* beta since 2014 is 0.77 and has ranged from 0.56 to 0.92. Prior to the recent pandemic, the high end of this range was 0.75.

In addition to *Value Line*, I have also included adjusted beta estimates as provided by Market Intelligence's Beta Generator Model. This model relied on a five-year period on a weekly basis ending October 13, 2023. The average and median Market Intelligence betas are 0.85 and 0.84, respectively. Market Intelligence betas as calculated using its Beta Generator Model are adjusted using the Vasicek method and calculated using the S&P 500 as the proxy for the investable market. This is in stark contrast with the *Value Line* beta estimates that are adjusted using a constant weighting of 67%/35% to the raw beta/market beta and use the New York Stock Exchange as the proxy for the investable market. Because I rely on the S&P 500 to estimate the expected return on the investable market, it makes sense to rely on beta estimates that are calculated using the S&P 500 as the benchmark for the market. Further, as S&P explains:

> The Vasicek Method is a superior alternative to the Bloomberg Beta adjustment. The Bloomberg adjustment is not appropriate for a vast number of situations, as it assigns constant weighting regardless of the standard error in the raw beta estimation (Bloomberg Beta = 1/3*market beta + 2/3*Raw Beta). Given the statistical fact that a larger sample size yields a smaller error, the Vasicek method more appropriately adjusts the raw beta via weights determined by the variance of the individual security versus the variance of a larger sample of comparable companies. The weights are designed to bring the raw beta closer to whichever beta estimation has the smallest error. This is a feature the Bloomberg beta cannot replicate.[32]

Q HOW DID YOU DERIVE YOUR MARKET RISK PREMIUM ESTIMATES?

A My market risk premium estimates are derived using two general approaches: a risk premium approach and a DCF approach. I also consider the normalized market risk

---

[32] S&P Market Intelligence, Beta Generator Model. Notably, while S&P makes reference to the Bloomberg method of applying 2/3 and 1/3 weights to the raw beta and market beta, respectively, the comparison still applies to *Value Line's* methodology of applying 67% and 35% weights. Both methods are forms of the Blume adjustment. While the weights are slightly different between the Bloomberg and *Value Line* methods, they are similar and apply a constant weight without any regard to accuracy. As such, the criticisms of the betas offered by S&P apply to both Bloomberg betas and *Value Line* betas.

premium of 5.50% with the normalized risk-free rate of 4.58% as recommended by Kroll, formerly known as Duff & Phelps.

Q PLEASE DESCRIBE YOUR MARKET RISK PREMIUM ESTIMATE DERIVED USING THE RISK PREMIUM METHODOLOGY.

A The forward-looking risk premium-based estimate was derived by estimating the expected return on the market (as represented by the S&P 500) and subtracting the risk-free rate from this estimate. I estimated the expected return on the S&P 500 by adding an expected inflation rate to the long-term historical arithmetic average real return on the market. The real return on the market represents the achieved return above the rate of inflation.

The Kroll *2023 SBBI Yearbook* estimates the historical arithmetic average real market return over the period 1926 to 2022 to be 8.90%.[33] A current consensus for projected inflation, as measured by the Consumer Price Index ("CPI"), is 2.30%.[34] Using these estimates, the expected market return is 11.40%.[35] The market risk premium then is the difference between the 11.40% expected market return and the projected risk-free rate of 4.00%, or 7.40%.

Q PLEASE DESCRIBE YOUR MARKET RISK PREMIUM ESTIMATES DERIVED USING THE DCF METHODOLOGY.

A I employed two versions of the constant growth DCF model to develop estimates of the market risk premium. I first employed the Federal Energy Regulatory Commission's

---

33 Kroll, 2023 SBBI Yearbook at 138.
34 Blue Chip Financial Forecasts, October 2, 2023 at 2.
35 [(1 +8.90%) ∗ (1 + 2.30%) - 1] ∗ 100.

("FERC") method of estimating the expected return on the market that was established in its Opinion No. 569-A. FERC's method for estimating the expected return on the market is to perform a constant growth DCF analysis on each of the dividend paying companies of the S&P 500 index. The growth rate component is based on the average of the growth projections excluding companies with growth rates that were negative or greater than 20%.[36] The weighted average growth rate for the remaining companies is 9.50%. After reflecting the FERC prescribed method of adjusting the dividend yield by (1+ 0.5g), the weighted average expected dividend yield is 2.20%. Thus, the DCF-derived expected return on the market is the sum of those two components, or 11.70%. The market risk premium then is the expected market return of 11.70% less the projected risk-free rate of 4.00%, or approximately 7.70%.

My second DCF-based market risk premium estimate was derived by performing the same DCF analysis described above, except I used all companies in the S&P 500 index rather than just the dividend paying companies. The weighted average growth rate for these companies is 10.20%. After reflecting the FERC prescribed method of adjusting the dividend yield by (1+ 0.5g), the weighted average expected dividend yield is 1.79%. Thus, the DCF-derived expected return on the market is the sum of those two components, or 11.99%. The market risk premium then is the expected market return of 11.99% less the projected risk-free rate of 4.00%, or 8.00%.

The average expected market return based on the DCF model is 11.85% and the average market risk premium based on the two DCF estimates is 7.85%.

---

[36] Opinion No. 569-A, at p. 210.

Q HOW DO YOUR EXPECTED MARKET RETURNS COMPARE TO CURRENT EXPECTATIONS OF FINANCIAL INSTITUTIONS?

A As shown in Table CCW-10, my average expected market return of 11.11%[37] exceeds long-term market expectations of several financial institutions.

TABLE CCW-10

Long-Term Expected Return on the Market

Source	Term	Expected Return Large Cap Equities
BlackRock Capital Management[1]	30 Years	8.20%
JP Morgan Chase[2]	10 - 15 Years	7.90%
Vanguard[3]	10 Years	4.7% - 6.7%
Research Affiliates[4]	10 Years	5.80%

Sources:
[1]BlackRock Investment Institute, September 2022 report.
[2]JP Morgan Chase, Long-Term Capital Market Assumptions, 2023 Report.
[3]Vanguard economic and market outlook for 2023: Beating back inflation.
[4]Research Affiliates, Asset Allocation Interactive. Retrieved 12/31/2022.

When compared to the expected market returns of financial institutions above, my average expected market return of 11.11% is more than two times higher than all

[37] 11.11% = (10.08% + 11.85% + 11.40%) / 3.

but one projection. For these reasons, my expected market returns, and the associated market risk premiums, should be considered reasonable, if not high-end estimates.

Q HOW DO YOUR ESTIMATED MARKET RISK PREMIUMS COMPARE TO THAT ESTIMATED BY KROLL?

A The Kroll analysis indicates a market risk premium falls somewhere in the range of 5.50% to 7.17%. My market risk premium estimates are in the range of 5.50% to 7.85%.

Q HOW DOES KROLL MEASURE A MARKET RISK PREMIUM?

A Kroll's range is based on several methodologies. First, Kroll estimated a market risk premium of 7.17% based on the difference between the total market return on common stocks (S&P 500) less the income return on 20-year Treasury bond investments over the 1926-2022 period.[38]

Second, Kroll used the Ibbotson & Chen supply-side model which produced a market risk premium estimate of 6.35%.[39] Kroll explains that the historical market risk premium based on the S&P 500 was influenced by an abnormal expansion of P/E ratios relative to earnings and dividend growth. In order to control for the volatility of extraordinary events and their impacts on P/E ratios, Kroll takes into consideration the three-year average P/E ratio as the current P/E ratio. Therefore, Kroll adjusted this market risk premium estimate to normalize the growth in the P/E ratio to be more in line with the growth in dividends and earnings.

---

[38] Kroll, 2023 SBBI Yearbook at 191.
[39] *Ibid.* at 199.

Finally, Kroll develops its own recommended equity, or market risk premium, by employing an analysis that takes into consideration a wide range of economic information, multiple risk premium estimation methodologies, and the current state of the economy by observing measures such as the level of stock indices and corporate spreads as indicators of perceived risk. Based on this methodology, and utilizing a "normalized" risk-free rate of 4.58%, Kroll concludes that the current expected, or forward-looking, market risk premium is 5.50%, implying an expected return on the market of 10.08%.[40]

Q WHAT ARE THE RESULTS OF YOUR CAPM ANALYSIS?

A As shown in Exhibit OPC (C)-16, I have provided the results of nine different applications of the CAPM. The first three results presented are based on the proxy group's current average *Value Line* beta of 0.92. The results of the CAPM based on these inputs range from 9.64% to 11.23%.

The next set of three results presented are based on the proxy group's historical *Value Line* beta of 0.77. The results of the CAPM based on these inputs range from 8.82% to 10.05%.

The last set of three results presented are based on the proxy group's current S&P Global Market Intelligence beta of 0.85. The results of the CAPM based on these

---

40 Kroll, *Kroll Increases U.S. Normalized Risk-Free Rate from 3.0% to 3.5%, but Spot 20-Year U.S. Treasury Yield Preferred When Higher*, June 16, 2022. Kroll's method uses the greater of 3.50% or current 20-year Treasury yields as the risk-free rate.

inputs range from 9.24% to 10.65%. My CAPM results are summarized in Table CCW-11.

TABLE CCW-11

CAPM Results Summary

Description	Current VL Beta	Historical VL Beta	Current MI Beta
D&P Normalized Method	9.64%	8.82%	9.24%
Risk Premium Method	10.82%	9.70%	10.27%
FERC DCF	11.23%	10.05%	10.65%

Q **WHAT IS YOUR RECOMMENDED RETURN FOR THE COMPANY BASED ON YOUR CAPM?**

A As I explain above, the current *Value Line* beta estimates are heavily impacted by the market fallout in early 2020 as a result of the COVID-19 pandemic, and likely do not reflect current investor expectations. Based on the results summarized above, I recommend a CAPM return estimate of 9.80%.

I. Return on Equity Summary

Q **BASED ON THE RESULTS OF YOUR RETURN ON COMMON EQUITY ANALYSES DESCRIBED ABOVE, WHAT RETURN ON COMMON EQUITY DO YOU RECOMMEND FOR THE COMPANY?**

A The results of my analyses are summarized in Table CCW-12.

TABLE CCW-12

Return on Common Equity Summary

Description	Results
DCF	9.20%
Risk Premium	9.90%
CAPM	9.80%

Based on my analyses described above, I estimate the Company's current market cost of equity to be in the reasonable range of 9.20% to 9.90%. Should the Commission order Pepco to operate under a traditional test year scenario without the BSA decoupling mechanism, I would recommend that Pepco be authorized an ROE of 9.55%, which is the midpoint of my recommended range.[41] Should the Commission allow Pepco to continue under a MYRP and/or the BSA, I recommend an ROE of 9.35%, which is in the lower half of my range (i.e. 9.20% to 9.55%). This point estimate is 20 basis points below the midpoint of my recommended range and is consistent with the findings of this Commission's Order and Opinion in Formal Case No. 1156. This recommendation is further supported by Pepco's lower financial risk and higher credit ratings relative to the proxy group.

---

[41] The midpoint is defined as the average of the low-end and high-end point estimates of my recommended range.

V. RESPONSE TO MR. ADRIEN MCKENZIE

A. Summary of Rebuttal to Mr. McKenzie

Q WHAT RETURN ON COMMON EQUITY IS PEPCO PROPOSING FOR THIS PROCEEDING?

A In his direct testimony, Mr. McKenzie's proxy group results produce a return on equity range of 9.9% to 11.1%, with a point estimate of 10.5%. In his supplemental direct testimony under a traditional test year, Mr. McKenzie reiterated his initial recommended range and ROE for Pepco.

Q HOW DID MR. MCKENZIE DEVELOP HIS ROE RANGE?

A Mr. McKenzie developed his ROE recommendation based on the results of his applications of the DCF, traditional CAPM, and a Risk Premium model. Further, he references the results of an Expected Earnings analysis and a non-utility DCF analysis as an attempt to corroborate his results.

Table CCW-13 below shows the average results of Mr. McKenzie's analyses that he relies on to conclude that a ROE in the range of 9.90% to 11.10%, with a point of 10.50%, is reasonable for Pepco. However, as I demonstrate throughout the balance of my testimony, reasonable adjustments to Mr. McKenzie's analyses reduce his ROE estimate for Pepco to no higher than my recommended ROE of 9.35%.

TABLE CCW-13

Mr. McKenzie's ROE Analysis

Model	**Average (1)**
DCF	8.9% - 10.0%
CAPM	11.1%
ECAPM	11.3%
Utility Risk Premium	10.6%
Expected Earnings	11.3%
Non-Utility DCF	10.2% - 10.5%
Range	9.9% - 11.1%
Recommended ROE	**10.50%**

Source: Exhibit PEPCO (F)-2.

Q PLEASE SUMMARIZE YOUR GENERAL CONCERNS WITH MR. MCKENZIE'S ANALYSES AND DETERMINATIONS.

A Mr. McKenzie developed there are several flaws with each of his methods that inherently bias his model results and recommendations upwards. For example:

- His DCF is biased upward because he (1) arbitrarily removes what he has determined to be 15 low-end outliers and one high-end outlier, and (2) he relies heavily on the midpoint of the individual results as a measure of central tendency. The more reasonable approach would be to not remove any outliers and rely on the median as a measure of central tendency.

- His CAPM is inflated by his inclusion of a size adjustment, an excessive market risk premium, and sole reliance on inflated Value Line beta estimates. He should have considered multiple measures of the market risk premium and beta values. He has not demonstrated that the size adjustment is applicable to price-regulated utilities.

- His ECAPM shares the same flaws identified above with respect to his CAPM. In addition to those flaws, he incorrectly includes an adjusted beta value from Value Line in the application of the ECAPM. The more accurate method would be to use an unadjusted beta.

- His utility bond yield plus risk premium method is overstated as a result of an arbitrary projected Baa utility bond yield that he develops on his own, does not account for interest rate projections to decline, and relies on an overly simplistic linear regression model that overstates a utility equity risk premium.

- His Expected Earnings analysis is not a market based measure of the cost of equity and has been rejected several times.

- His non-utility proxy group DCF is applied to 33 non-regulated companies that do not share underlying business risks similar to Pepco and could be based on highly profitable and speculative companies. This violates the Hope & Bluefield standards and should be rejected.

- In addition, Mr. McKenzie's recommended ROE of 10.50% falls significantly outside a reasonable range for a low-risk distribution electric utilities when compared to observable benchmarks such as recent authorized ROEs for electric utilities, especially considering the lower-risk nature of distribution-only electric utilities that operate under a MYP.

B. Mr. McKenzie's DCF

Q PLEASE DESCRIBE MR. MCKENZIE'S DCF ANALYSIS.

A Mr. McKenzie applied the traditional DCF model to his utility proxy group. Mr. McKenzie observed the average and midpoint results of his proxy group's DCF results. He relied on earnings growth rates from *Value Line*, IBES, and Zacks. In addition to analyst growth rates from the aforementioned providers, he also estimated a sustainable growth rate based on Value Line data in a similar fashion to my sustainable growth DCF model described above. Mr. McKenzie makes reference to the average and midpoint estimates of his results after excluding what he has deemed to be outliers. The average DCF results from his four iterations fall in the range of 8.9% to 10.0% for his proxy group.[42] He also considers the midpoint of his proxy group's DCF results after he excludes outliers.

Q DO YOU HAVE ANY ISSUES WITH MR. MCKENZIE'S DCF ANALYSIS?

A Yes, I have two concerns with Mr. McKenzie's DCF analysis. First, I disagree with his use of the midpoint of his proxy group's individual DCF results as the midpoint of the raw individual results are generally not an accurate method of measuring the central tendency.

In addition, I disagree with Mr. McKenzie's proposal to selectively exclude what he believes to be outliers from the proxy group which has the effect of manipulating the results of the proxy group. Notably, he excludes 15 low-end results from his DCF analysis, while only removing one outlier for being too high. Mr. McKenzie simply narrows the range of the proxy group results to produce a result which he finds to be reasonable.

A better methodology would be to rely on all the results of the proxy group, by assessing the central tendency of the proxy group results. In the presence of outliers, a

[42] Exhibit PEPCO (F)-5.

more accurate method of measuring the central tendency of the proxy group's results would be to measure the median of all the DCF return estimates.

Q CAN YOU PROVIDE AN EXAMPLE OF WHY THE MIDPOINT IS NOT A GOOD MEASURE OF CENTRAL TENDENCY FOR A SAMPLE OF INDIVIDUAL OBSERVATIONS?

A Yes. Real life examples can be household incomes or even housing values. For instance, let us assume the lowest priced home available for sale in the United States is $100,000 while the highest priced home available is $25 million (notably, this is approximately $163 million lower than the highest priced home that sold in the United States last year). The midpoint of these two figures is $12.55 million, which is nearly 30x higher than the recently reported median home sales price of approximately $437,000.

Q CAN MR. MCKENZIE'S DCF ANALYSIS BE ADJUSTED TO PRODUCE A REASONABLE RETURN ON EQUITY FOR PEPCO?

A Yes. Instead of eliminating individual results, measuring the median without excluding what he has determined to be outlier results is the appropriate method. The median DCF results for his electric proxy group without exclusions is in the range of 8.4% to 9.5%. The average of the unadjusted median results for his electric group is 9.15%.

C. Mr. McKenzie's Traditional CAPM

Q PLEASE DESCRIBE MR. MCKENZIE'S TRADITIONAL CAPM ANALYSIS.

A Mr. McKenzie developed a traditional CAPM analysis based on current Treasury bond yields. His current bond yield of approximately 3.7% is measured as the average for the six months ended January 2023.[43] To estimate the market risk premium, Mr. McKenzie begins with performing a constant growth DCF analysis to the dividend paying companies of the S&P 500. Mr. McKenzie excluded companies from the DCF analysis that have growth rates less than 0.0% and greater than 20.0%. This produced an expected market return of 11.6%. From this market return estimate, he subtracts his risk-free rate of 3.7% to arrive at a market risk premium of 7.9%.[44] He relies on the *Value Line* utility betas for the companies included in his proxy group to produce an average cost of equity 10.8%.[45]

Then he adjusts each of his CAPM return estimates to account for any size premium based on each company's market capitalization. This size adjustment has increased his proxy group's CAPM returns by an average of 30 basis points. Therefore, his size-adjusted traditional CAPM analysis produces an average result in the range of 11.1%.

Q IS MR. MCKENZIE'S CAPM ANALYSIS REASONABLE?

A No. I believe Mr. McKenzie's CAPM analysis is overstated for at least three reasons: (1) his expected return on the market of 11.6% is based on an unsustainable growth rate of 9.5%, causing a bias and does not include any consideration of the long-run average return on the market; (2) his sole reliance on Value Line betas is at odds with his use of the S&P 500 as the benchmark for the overall market and is heavily influenced by the market volatility from the Spring of 2020 as a result of the onset of the COVID-19

43 PEPCO (F)-7.
44 Exhibit PEPCO (F)-7.
45 *Id*.

pandemic, and; (3) his size adjustment is unreasonable and not shown to be applicable to utility stocks.

Q WHY DO YOU BELIEVE MR. MCKENZIE'S EXPECTED RETURN ON THE MARKET IS UNREASONABLE?

A Mr. McKenzie recognizes the need to apply multiple analytical methods for estimating the cost of equity[46], however, he only chose to apply, and consider the results of the constant growth DCF to estimate the cost of equity for the S&P 500. As Mr. McKenzie states in his testimony, "The DCF method, which is frequently referenced and relied on by regulators, is only one theoretical approach to evaluate the return investors require. There are a number of other accepted methodologies for estimating the cost of capital."[47] In fact, Mr. McKenzie even goes on to state that "while the DCF model is a recognized approach to estimating the ROE, it is not without shortcomings and does not otherwise eliminate the need to ensure that the end result is fair."[48]

To be consistent with his testimony, Mr. McKenzie should have implemented alternative measures of the expected market return and market risk premium. As Dr. Morin notes in his book, *New Regulatory Finance,*

> Although realized returns for a particular time period can deviate substantially from what was expected, it is reasonable to believe that long-run average realized returns provide an unbiased estimate of what were expected returns. This is the fundamental rationale behind the historical risk premium approach. Analysts and regulators often assume that the average historical risk premium over long periods is the best proxy for the future risk premium.[49]

---

46 McKenzie Direct at 31.
47 *Id.*
48 *Id.* at 32.
49 Morin, Dr. Roger A, "New Regulatory Finance," at p. 156.

In his book, Dr. Morin concludes that "[t]here are two broad approaches to estimating the risk premium: retrospective and prospective. Each has its own strengths and weaknesses, hence the need to utilize both methods."[50] As such, Mr. McKenzie should have considered the results of multiple estimates of the expected market return from multiple methods. Examples of other such methods are described above in reference to my application of the CAPM.

Q WHY DO YOU FIND MR. MCKENZIE'S SOLE RELIANCE ON VALUE LINE BETAS IN HIS CAPM ANALYSIS TO BE INAPPROPRIATE?

A As I explain above, my CAPM analysis relies on beta estimates from Value Line and S&P Global Market Intelligence's Beta Generator model. There are two distinct differences between the MI Beta I relied on and the Value Line Beta: (1) the benchmark index used as the proxy for the market in the MI Beta estimates is the S&P 500 whereas *Value Line* relies on the New York Stock Exchange ("NYSE"); and (2) the MI Betas I used are adjusted using the Vasicek method whereas the *Value Line* Betas are adjusted using a modified form of the Blume adjustment.

Because Mr. McKenzie is not presenting a CAPM analysis that relies on the NYSE as a proxy for the market, or the expected market return, which the market risk premium ("MRP") is calculated from, this alone makes the *Value Line* Betas less preferable. Betas employed in a CAPM should be calculated using the benchmark index that is also used as a proxy for the overall market. Mr. McKenzie and I both relied on

---

[50] *Id.* at p. 162.

the S&P 500 as the proxy for the overall market in estimating our MRP. While *Value Line* Betas are commonly used in CAPM analyses presented in regulatory proceedings such as this one, it is theoretically incorrect to do so unless the NYSE is used as the proxy for the overall market used to calculate the MRP.

In addition, *Value Line* betas are based on five years of historical prices, meaning that the significant market volatility as a result of the COVID-19 pandemic is captured in his *Value Line* betas and considered "expected." It is not rational to "expect" a global pandemic going forward. As such, current *Value Line* betas should be viewed with skepticism and caution should be exercised when employing them in estimating the cost of capital at the current time.

Q WHY DO YOU FIND MR. MCKENZIE'S SIZE ADJUSTMENT INAPPROPRIATE?

A Mr. McKenzie's size adjustment ROE adder is based on estimates made by Kroll's Cost of Capital Navigator. Kroll estimates various size adjustments based on differentials in beta estimates tied to the size of a company. The main concern with these size adjustments as applied by Mr. McKenzie, is that they are not based on risk comparable companies relative to the utility industry or the Company. In addition, there is empirical evidence which concludes that, while size premiums are present in industrial companies, such a size premium is not present in utility companies, nor are they appropriate to include in valuing utilities.[51]

---

[51] Wong, Annie, 1993, Utility stocks and the size effect: An empirical analysis, Journal of the Midwest Finance Association, 95-101.

Q CAN MR. MCKENZIE'S CAPM ANALYSIS BE ADJUSTED TO PRODUCE MORE REASONABLE RESULTS?

A Yes. The following adjustments are necessary: (1) reflecting more recent data for the DCF on the market (11.85%); (2) include other estimates of the expected return on the market such as the normalized cost of equity from Kroll (10.08%) and the expected return based on the historical real return adjusted for projected inflation (11.40%); (3) eliminating his size adjustments; and (4) incorporating beta estimates that are calculated relative to the S&P 500 such as those presented in my CAPM analysis.

Reflecting more recent estimates of the DCF return on the market as well as including the two additional estimates of the expected return on the market produce an average expected return of 11.11%.[52] Subtracting his risk-free rate from this expected return on the market, produces market risk premium of 7.4%. Notably, this market risk premium is consistent with the empirical evidence discussed in Dr. Morin's *Modern Regulatory Finance.*[53] Applying these market risk premiums to his proxy group's average *Value Line* beta of 0.90 produces average CAPM results of 10.36%. Similarly, applying the same market risk premium to the proxy group's average historical average *Value Line* beta since 2014 of 0.77 as provided in my CAPM analysis, produces CAPM results of 9.40%.

---

52 11.11% = (10.08% + 11.85% + 11.40%) / 3

53 Dr. Morin notes in his new textbook, that the market risk premium "most likely falls within a range of 6% - 8%", Morin, Dr. Roger A, *Modern Regulatory Finance,* at p. 178.

Q DID MR. MCKENZIE ALSO PERFORM AN ECAPM ANALYSIS?

A Yes. Mr. McKenzie performed an ECAPM analysis that relied on the same current risk-free rate of 3.7%, on the same market risk premium of 7.9%, and the same average *Value Line* beta that he used in his traditional CAPM analyses.

He then uses an ECAPM model that applies a 25% weighting factor to the market beta of 1, and a 75% weighting factor to the utility group beta. This produces an average ECAPM of 11.0%.

Finally, Mr. McKenzie applied the same size adjustment of approximately 0.3% to his utility group's ECAPM estimates to produce a size-adjusted average of 11.3%.[54]

Q ARE MR. MCKENZIE'S CURRENT AND PROJECTED ECAPM ANALYSES REASONABLE?

A No. Mr. McKenzie's ECAPM analyses share all of the same flaws as his traditional CAPM analyses. More importantly, Mr. McKenzie's proposal to apply an ECAPM while using adjusted betas published by Value Line inflates his results. Mr. McKenzie's analysis and results should be disregarded.

Q PLEASE EXPLAIN THE ISSUES YOU HAVE WITH MR. MCKENZIE'S CURRENT AND PROJECTED ECAPM ANALYSES.

A Mr. McKenzie's ECAPM analysis is flawed because his model was developed using adjusted utility betas. An ECAPM analysis flattens the security market line, and is designed for raw beta estimates, not adjusted betas such as the ones published by *Value*

---

54 PEPCO (F)-8.

Line. Beta adjustments, on their own, accomplish virtually the same thing as an ECAPM analysis. They flatten the security market line and increase the intercept at the risk-free rate. An ECAPM analysis is not designed to be used with adjusted betas, but rather is designed to be used with unadjusted betas. Mr. McKenzie's proposal to use adjusted betas within an ECAPM analysis is unreasonable and double counts the attempt to flatten the security market line and increase CAPM return estimates for companies with betas below 1, and decrease CAPM return estimates for companies with betas greater than 1.

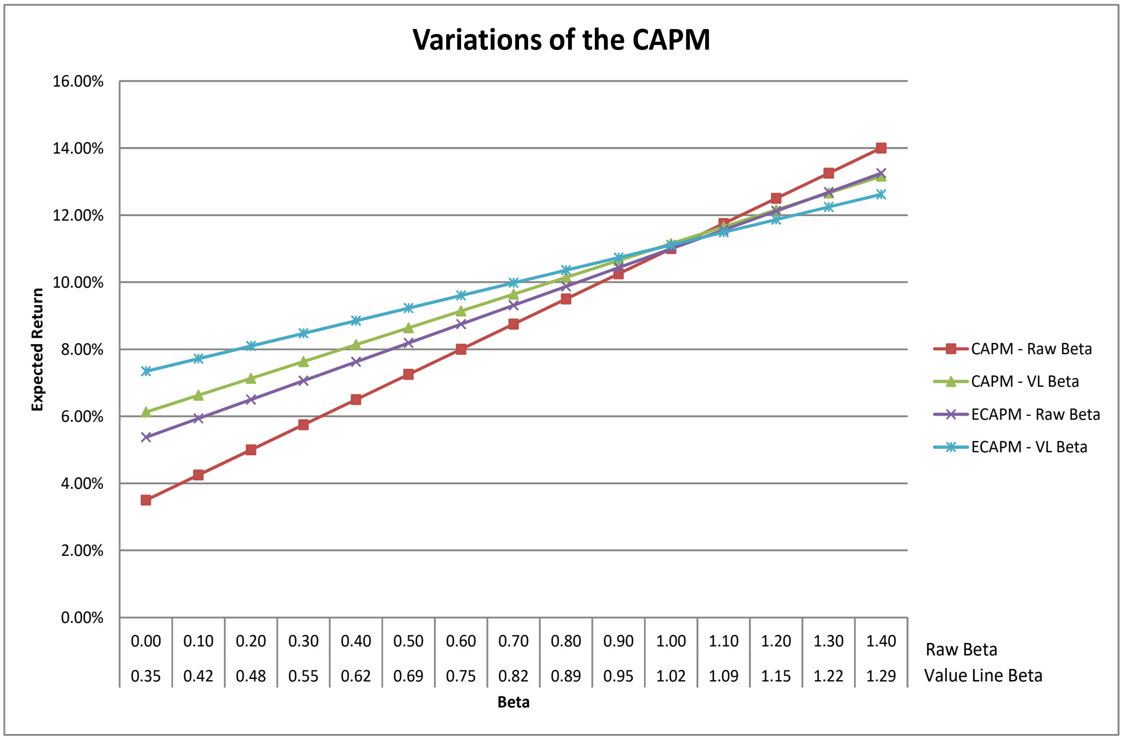
Q DO YOU HAVE ANY ADDITIONAL COMMENTS REGARDING THE ECAPM AND ADJUSTED BETAS?

A Yes. The notion that an adjustment to beta is still necessary when applying the ECAPM adjustment is not true. The *Value Line* beta adjustment alters the CAPM return at both the vertical axis (the intercept point) and the horizontal axis, the slope of the CAPM return line (along the horizontal axis). This is depicted in Figure CCW-5 below.

As shown in Figure CCW-5, I have modeled the expected returns at various levels of raw beta using both the traditional CAPM and ECAPM methodologies assuming a risk-free rate of 3.50%, and a market risk premium of 7.50%. I also show the expected CAPM and ECAPM returns using the associated adjusted (*Value Line*) beta estimates for each raw beta estimate. As shown in Figure CCW-5, the impact on the traditional CAPM return using a raw beta and a traditional CAPM using an adjusted beta has the effect of increasing the intercept point at a zero raw beta (y-axis) from: (1) risk-free rate to (2) the combination of the risk-free rate plus 35% of the market risk premium. Further, as the unadjusted beta is increased above zero, the adjusted beta increases the CAPM return when the raw beta is less than one, and decreases the CAPM return when the raw beta is greater than one. In other words, the beta adjustment raises the CAPM return at the vertical axis point and flattens the security market across the horizontal axis as the raw beta increases above zero.

The ECAPM using raw betas has the same impact on the traditional CAPM using an adjusted beta: the ECAPM increases the CAPM return at a zero raw beta from: (1) the risk-free rate, to (2) the risk-free rate plus 25% of the market risk premium. Further, the ECAPM using raw betas flattens the traditional CAPM return line across the horizontal axis as the raw betas increase above zero.

FIGURE CCW-5



Assumptions:
Market Risk Premium is 7.50%
Risk-Free Rate is 3.50%

As shown in the graph above, compared to the traditional CAPM using a raw beta, the traditional CAPM using an adjusted beta raises the intercept point (a y-axis impact) and flattens the slope of the security market line (an x-axis impact). Similarly, using a raw beta estimate, the ECAPM raises the intercept point at the y-axis and flattens the CAPM return for all raw beta estimates.

Significantly, if an adjusted beta is used in an ECAPM return model, the CAPM return at the y axis increases from: (1) the risk-free rate, up to (2) the risk-free rate plus approximately 51% of the market risk premium. Further, the CAPM return for betas less than one starts at an inflated y-axis intercept point and increases as the raw beta increases above zero.

Mathematically, *Value Line*'s beta adjustments produce nearly the same effect on the estimated CAPM return as does an ECAPM using a raw beta. Using an adjusted beta in an ECAPM model, as Mr. McKenzie has proposed, produces a flawed and inflated CAPM return estimate. Mr. McKenzie's ECAPM analysis should be rejected in its entirety.

D. Utility Risk Premium

Q PLEASE DESCRIBE MR. MCKENZIE'S UTILITY EQUITY RISK PREMIUM ANALYSIS.

A Mr. McKenzie's utility equity risk premium analysis is presented in his Exhibit PEPCO (F)-9. As shown on these exhibits, Mr. McKenzie measured the annual equity risk premium over the period of 1974 through 2022 by subtracting the average utility bond yield from the average authorized ROE. This produces an average equity risk premium of 3.89%.

Mr. McKenzie then performs a regression analysis to measure the inverse relationship between interest rates and equity risk premiums. Using this regression analysis, Mr. McKenzie adjusts his equity risk premium from 3.89%, up to 4.93% based on current utility bond yields.[55] He then adds these adjusted equity risk premiums to the current Baa-rated utility bond yields of 5.39%. This method produces a ROE in the range of 10.59%.[56]

---

[55] Exhibits PEPCO (F)-9.
[56] *Id*.

Q DO YOU HAVE ANY CONCERNS WITH MR. MCKENZIE'S UTILITY EQUITY RISK PREMIUM?

A Yes. My main concerns with his utility equity risk premium analysis are: (1) his exclusive reliance on Baa-rated utility bond yields; (2) his use of a simple inverse relationship to estimate an equity risk premium through changes in interest rates, and; (3) his result produces an estimate higher than the average ROE for electric distribution utilities in any year that had at least three rate case decisions dating back to 2001.

As I explain above, Mr. McKenzie adds current Baa-rated utility bond yields to his adjusted equity risk premium. Mr. McKenzie's analysis fails to acknowledge that Pepco is not a Baa/BBB rated utility. Rather, Pepco is a split-rated utility with Baa1/A- ratings. Mr. McKenzie's sole reliance on Baa-rated utility bond yields overstates the cost of equity for Pepco.

As I explain above, because the risk premium can vary depending upon market conditions and changing investor risk perceptions, I believe using an estimated range of risk premiums provides the best method to measure the current return on common equity for a risk premium methodology. In my opinion, measuring the five-year and ten-year rolling average risk premiums over the study period are a reasonable method of estimating the equity risk premium. These rolling average risk premiums mitigate the impact of anomalous market conditions and skewed risk premiums over an entire business cycle. Based on more recent data and my estimates of the equity risk premium detailed above, a more comprehensive Risk Premium-derived ROE estimate is 9.9%.

E. Mr. McKenzie's Expected Earnings

Q PLEASE DESCRIBE MR. MCKENZIE'S EXPECTED EARNINGS ANALYSIS.

A As shown on his Direct Exhibit PEPCO (F)-10, Mr. McKenzie's expected earnings analysis is based on *Value Line*'s projected earned return on book equities for his proxy group, adjusted to reflect average year equity returns. Based on a review of projected earnings over the next three to five years, Mr. McKenzie estimates an average ROE of 11.3%.

Q IS THE EXPECTED EARNINGS ANALYSIS A REASONABLE METHOD FOR ESTIMATING A FAIR ROE FOR THE COMPANY?

A No. An expected earnings analysis does not measure the return an investor requires in order to make an investment. In other words, the accounting measure of the earned ROE does not measure the opportunity cost of capital. Rather, it measures the earned return on book equity that companies have experienced in the past or are projected to achieve in the future. The returns investors require in order to assume the risk of an investment are measured from prevailing stock market prices.

In addition, FERC has recently found that the Expected Earnings model does not satisfy the requirements of *Hope*. In part, FERC states as follows:

> As a result, the expected return on a utility's book value does not reflect "returns on investments in other enterprises" because book value does not reflect the value of any investment that is available to an investor in the market, outside of the unlikely situation in which market value and book value are exactly equal. Accordingly, we find that relying on the Expected Earnings model would not satisfy the requirements of *Hope*.
>
> The return on book value is also not indicative of what return an investor requires to invest in the utility's equity or what return an investor receives on the equity investment, because those returns are determined

> with respect to the current market price that an investor must pay in order to invest in the equity.[57]

Later in the same Opinion, FERC observes that Expected Earnings model does not identify investments of comparable risk. It states as follows:

> Moreover, we find that the record demonstrates that the Expected Earnings model does not identify investments of comparable risk and which alternatives will have a higher expected return as MISO TOs' witness Mr. McKenzie indicates.[footnote omitted] In particular, because the Expected Earnings model measures returns on book value, without consideration of what market price an investor would have to pay to invest in the relevant company, it does not accurately measure the investor's expected returns on its investment.[58]

Additionally, the historical and projected earned ROE for these holding companies can be significantly influenced by the financial performance of nonregulated operations. For these reasons, Mr. McKenzie's expected earnings analysis should be disregarded.

F. Non-Utility DCF

Q DO YOU HAVE ANY ADDITIONAL COMMENTS IN REGARDS TO MR. MCKENZIE'S RETURN ESTIMATES?

A Yes. Mr. McKenzie also performed a DCF model on a proxy group of 33 non-regulated companies, which he found to be a reasonable risk proxy for Pepco. The average adjusted DCF results fall within the range of 10.2% to 10.6%. Mr. McKenzie opines that the analysis is relevant in evaluating a fair ROE for the Company.[59] I disagree with his assessment. However, because Mr. McKenzie did not rely on these results in

---

[59] McKenzie Direct at 53.

developing his inflated recommendation, I will not comment on his non-utility analysis any further.

Q DOES THIS CONCLUDE YOUR DIRECT TESTIMONY?

A Yes, it does.

Qualifications of Christopher C. Walters

Q PLEASE STATE YOUR NAME AND BUSINESS ADDRESS.

A Christopher C. Walters. My business address is 16690 Swingley Ridge Road, Suite 140, Chesterfield, MO 63017.

Q PLEASE STATE YOUR OCCUPATION.

A I am a consultant in the field of public utility regulation and a Principal with the firm of Brubaker & Associates, Inc. ("BAI"), energy, economic and regulatory consultants.

Q PLEASE STATE YOUR EDUCATIONAL BACKGROUND AND PROFESSIONAL EMPLOYMENT EXPERIENCE.

A I received a Bachelor of Science Degree in Business Economics and Finance from Southern Illinois University Edwardsville. I have also received a Master of Business Administration Degree from Lindenwood University.

As a Principal at BAI, I perform detailed technical analyses and research to support regulatory projects including expert testimony covering various regulatory issues. Since my career at BAI began in 2011, I have held the positions of Analyst, Associate Consultant, Consultant, Senior Consultant, and Associate. Throughout my tenure, I have been involved with several regulated projects for electric, natural gas and water and wastewater utilities, as well as competitive procurement of electric power and gas supply. My regulatory project work includes estimating the cost of equity capital, capital structure evaluations, assessing financial integrity, merger and acquisition related issues, risk management related issues, depreciation rate studies, and other revenue requirement issues.

BAI was formed in April 1995. BAI and its predecessor firm have participated in more than 700 regulatory proceedings in 40 states and Canada.

BAI provides consulting services in the economic, technical, accounting, and financial aspects of public utility rates and in the acquisition of utility and energy services through RFPs and negotiations, in both regulated and unregulated markets. Our clients include large industrial and institutional customers, some utilities and, on occasion, state regulatory agencies. We also prepare special studies and reports, forecasts, surveys and siting studies, and present seminars on utility-related issues.

In general, we are engaged in energy and regulatory consulting, economic analysis and contract negotiation. In addition to our main office in St. Louis, the firm also has branch offices in Corpus Christi, Texas; Detroit, Michigan; Louisville, Kentucky and Phoenix, Arizona.

Q HAVE YOU EVER TESTIFIED BEFORE A REGULATORY BODY?

A Yes. I have sponsored testimony before state regulatory commissions including: Arizona, Arkansas, Colorado, Delaware, Florida, Georgia, Illinois, Iowa, Kansas, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Missouri, Montana, Nevada, New Mexico, North Carolina, Ohio, Oklahoma, Oregon, South Carolina, Texas, Utah, and Wyoming. In addition, I have also sponsored testimony before the City Council of New Orleans and an affidavit before the FERC.

Q PLEASE DESCRIBE ANY PROFESSIONAL REGISTRATIONS OR ORGANIZATIONS TO WHICH YOU BELONG.

A I earned the Chartered Financial Analyst ("CFA") designation from the CFA Institute. The CFA charter was awarded after successfully completing three examinations which covered the subject areas of financial accounting and reporting analysis, corporate finance, economics, fixed income and equity valuation, derivatives, alternative investments, risk management, and professional and ethical conduct. I am a member of the CFA Institute and the CFA Society of St. Louis.

Sources:
The current year P/E ratio is based on the forward P/E (price over expected earnings per share). All historical year P/E ratios are based on annual average share price over achieved earnings per share.
[1] Data for years 2019 and prior were retreived from the Value Line Investment Survey Investment Analyzer Software, downloaded on June 18, 2021.
Data for the years 2020 - 2022 was retrieved from Value Line Investment Surveys.

Sources:
The current year P/E ratio is based on the forward P/E (price over expected earnings per share). All historical year P/E ratios are based on annual average share price over achieved earnings per share.
[1] Data for years 2019 and prior were retreived from the Value Line Investment Survey Investment Analyzer Software, downloaded on June 18, 2021.
Data for the years 2020 - 2022 was retrieved from Value Line Investment Surveys.
[2] The Value Line Investment Survey, July 21, August 11, and September 8, 2023.

Note:
[a] Based on the average of the high and low price and the projected Cash Flow per share.

Sources:
The current year P/E ratio is based on the forward P/E (price over expected earnings per share). All historical year P/E ratios are based on annual average share price over achieved earnings per share.
[1] Data for years 2019 and prior were retreived from the Value Line Investment Survey Investment Analyzer Software, downloaded on June 18, 2021.
Data for the years 2020 - 2022 was retrieved from Value Line Investment Surveys.

I. INTRODUCTION

Q. PLEASE STATE YOUR NAME AND BUSINESS ADDRESS.

A. My name is Brian C. Andrews. My business address is 16690 Swingley Ridge Road, Suite 140, Chesterfield, Missouri 63017.

Q. WHAT IS YOUR OCCUPATION?

A. I am an Associate with Brubaker & Associates, Inc. ("BAI"), a firm of energy, economic and regulatory consultants specializing in the field of public utility regulation.

Q. PLEASE DESCRIBE YOUR EDUCATIONAL BACKGROUND AND RELEVANT EMPLOYMENT EXPERIENCE.

A. This information is included in Exhibit OPC (D)-1.

Q. ON WHOSE BEHALF ARE YOU APPEARING IN THIS PROCEEDING?

A. I am appearing in this proceeding on behalf of the Office of the People's Counsel for the District of Columbia ("OPC").

Q. HAVE YOU PREVIOUSLY FILED TESTIMONY BEFORE THE PUBLIC SERVICE COMMISSION OF THE DISTRICT OF COLUMBIA ("COMMISSION") REGARDING DEPRECIATION ISSUES?

A. Yes, I filed depreciation related testimony in Formal Case No. ("FC") 1162. I have also filed depreciation related testimony before the Public Service Commissions in Arizona, Arkansas, California, Colorado, Florida, Illinois, Indiana, Kentucky, Louisiana, Michigan, Missouri, Montana, New Mexico, Oklahoma, and South Carolina.

Q. DO YOU BELONG TO ANY PROFESSIONAL SOCIETIES?

A. Yes. I am a member and a Past President of the Society of Depreciation Professionals ("SDP").

Q. DO YOU HOLD ANY CERTIFICATIONS AS A DEPRECIATION EXPERT?

A. Yes. SDP has awarded me the designation of Certified Depreciation Professional ("CDP"). This certification is based upon my education, experience, and successful completion of the CDP Exam.

Q. WERE YOUR TESTIMONY AND EXHIBITS PREPARED BY YOU OR UNDER YOUR DIRECT SUPERVISION AND CONTROL?

A. Yes.

II. SUMMARY

Q. WHAT IS THE SCOPE AND PURPOSE OF YOUR DIRECT TESTIMONY IN THIS PROCEEDING?

A. The purpose of my testimony is to present OPC's proposed depreciation rates. I will provide my assessment of Potomac Edison Power Company's ("Pepco" or "Company") depreciation rates. OPC's proposed depreciation rates reflect adjustments to the average service lives ("ASL") assumed for several accounts, the net salvage rate for Account 362, and the use of the Handy-Whitman inflation rates to discount net salvage costs.

Q. PLEASE SUMMARIZE YOUR CONCLUSIONS AND RECOMMENDATIONS.

A. My conclusions and recommendations are as follows:

1. Pepco's proposed depreciation rates are excessive and burden its ratepayers with excessive depreciation expense. As proposed, Pepco's depreciation rates would be an 8.5% increase over the currently approved depreciation rates.

2. The ASLs that Pepco, through its witness, Mr. Ned Allis, is recommending for nine plant accounts should be lengthened. Statistical fitting methods indicate that survivor curves with longer ASLs fit Pepco's historic retirement data better than what has been proposed by Mr. Allis.

3. Pepco's proposed -30% net salvage rate for Account 362 is not supported by the most recent 10 years of retirement history. The -30% includes an excessive amount of net salvage accruals for Account 362. A more reasonable net salvage rate for Account 362 is -25%.

4. Pepco's proposal to use a uniform 2.5% inflation rate based on the Consumer Price Index ("CPI") in order to discount future net salvage costs using the DC Present Value Method should be rejected. The Handy-Whitman inflation rates specific to each Federal Energy Regulatory Commission's ("FERC") account should be utilized instead.

5. The Commission should reject Pepco's depreciation rates that have been presented in Exhibit Pepco (L)-1, as they produce an excessive level of depreciation expense and burden Pepco's ratepayers.

6. The Commission should approve OPC's proposed depreciation rates that have been presented in Exhibit OPC (D)-3.

7. OPC's proposed depreciation rates would reduce the traditional test year depreciation expense by $24.52 million.

8. OPC's proposed depreciation rates would reduce the multi-year test period depreciation expense by $26.37 million, $28.25 million, and $29.87 million in 2024, 2025, and 2026, respectively.

III. BOOK DEPRECIATION CONCEPTS

Q. PLEASE EXPLAIN THE PURPOSE OF BOOK DEPRECIATION ACCOUNTING.

A. Book depreciation is the recognition in a utility's income statement of the consumption or use of assets to provide utility service. Book depreciation is recorded as an expense and is included in the ratemaking formula to calculate the utility's overall revenue requirement.

The basic underlying principle of utility depreciation accounting is intergenerational equity, where the customers/ratepayers who benefit from the generated service of assets pay all the costs for those assets during the benefit period, which is over the life of those assets.[1] This concept of intergenerational equity can be achieved through depreciation by allocating costs to customers in a systematic and rational manner that is consistent with the period of time in which customers receive the service value.[2]

Book depreciation provides for the recovery of the original cost of the utility's assets that are currently providing service. Book depreciation expense is not intended to provide for replacement of the current assets, but provides for capital recovery or return of current investment. Generally, this capital recovery occurs over the ASL of the investment or assets. As a result, it is critical that appropriate ASLs be used to develop the depreciation rates so no generation of ratepayers is disadvantaged.

---

[1] Edison Electric Institute, Introduction to Depreciation for Public Utilities and Other Industries, April 2013, page viii.

[2] *Ibid.* at 22.

In addition to capital recovery, depreciation rates also contain a provision for net salvage. Net salvage is simply the scrap or reuse value less the removal cost of the asset being depreciated. Accordingly, a utility will also recover the net salvage costs over the useful life of the asset.

Q. ARE THERE ANY DEFINITIONS OF DEPRECIATION ACCOUNTING THAT ARE UTILIZED FOR RATEMAKING PURPOSES?

A. Yes. One of the most quoted definitions of depreciation accounting is the one contained in the Code of Federal Regulations:

> Depreciation, as applied to depreciable electric plant, means the loss in service value not restored by current maintenance, incurred in connection with the consumption of prospective retirement of electric plant in the course of service from causes which are known to be in current operation and against which the utility is not protected by insurance. Among the causes to be given consideration are wear and tear, decay, action of the elements, inadequacy, obsolescence, changes in the art, changes in demand and requirements of public authorities.[3]

Effectively, depreciation accounting provides for the recovery of the original cost of an asset, adjusted for net salvage, over its useful life.

Q. HOW ARE DEPRECIATION RATES DETERMINED?

A. Depreciation rates are determined using a depreciation system. There are three components, each with a number of variations, used to determine a depreciation system, which is then used to estimate depreciation rates. The three basic components are: methods, procedures, and techniques. The choice of a depreciation system can significantly affect the resulting depreciation rates.

---

[3] Electronic Code of Federal Regulations, Title 18, Chapter 1, Subchapter C, Part 101.

Q. PLEASE FURTHER DESCRIBE THE METHODS THAT ARE USED WITHIN A DEPRECIATION SYSTEM.

A. There generally are three types of methods of spreading the depreciation expense over the life of property. These are the Straight Line Method, Accelerated Methods, and Deferred Methods. The Straight Line Method is the method most widely used by utility companies for accounting and ratemaking purposes, as it is easy to apply and does not create intergenerational inequities because it spreads an equal portion of the plant cost across each accounting period. Accelerated Methods result in higher depreciation rates earlier in an asset's life, and lower depreciation rates later. Deferred Methods have increasing rates over an asset's life.

Q. PLEASE FURTHER DESCRIBE THE GROUPING PROCEDURES THAT ARE USED WITHIN A DEPRECIATION SYSTEM.

A. There are four main grouping procedures used within a depreciation system. These four procedures are the Individual Procedure, the Broad Group (more commonly known as the Average Life Group ("ALG")), the Vintage Group, and the Equal Life Group ("ELG").

In the ALG Procedure, all units within a particular account or category are assumed to be part of a single group that exhibits the same life and retirement characteristics. This is the most common utilized procedure.

The Vintage Group and the ELG Procedure assume that sub-groups within a particular account or category may exhibit unique life characteristics. As an example of the Vintage Group Procedure, it may assume that all poles installed in 1985 have a

50-year life, while all poles installed in year 1995 have a 45-year life. With the ELG Procedure, it may assume that all poles that are expected to have a life of 50 years should have one depreciation rate while poles that are expected to only attain life spans of 40 years would have a different depreciation rate. The overall group depreciation rate would be a composite of the ELG depreciation rates.

Q. PLEASE FURTHER DESCRIBE THE TECHNIQUES THAT ARE USED WITHIN A DEPRECIATION SYSTEM.

A. There are two techniques used to calculate depreciation rates: Whole Life and Remaining Life. The Whole Life Technique spreads the original cost less net salvage of the account over the average life of the account. This technique requires that separate amortizations be made to correct for over- and under-accumulations due to changes in an account's ASL.

The Remaining Life Technique spreads the unrecovered cost less net salvage over the remaining life of the account. The Remaining Life Technique is the most common technique used and it has a self-correcting nature that spreads any over- or under-accumulations over the remaining life.

Q. IN YOUR EXPERIENCE, WHAT DEPRECIATION SYSTEM IS MOST COMMONLY UTILIZED TO DETERMINE UTILITY DEPRECIATION RATES FOR RATEMAKING PURPOSES?

A. The most common depreciation system is one that consists of the Straight Line Method, the ALG Procedure, and the Remaining Life Technique.

Q. PLEASE EXPLAIN SURVIVOR CURVES AND THE NOTATION USED TO REFERENCE THEM.

A. The selection of the survivor curve is one of the most important aspects in conducting a depreciation study. A survivor curve is a visual representation of the amount of property existing at each age interval throughout the life of a group of property. From the survivor curve, parameters required to calculate depreciation rates can be determined, such as the ASL of the group of property and the composite remaining life. For assets with an assumed lifespan or retirement date, the survivor curve is used to estimate the interim retirements that will occur between the study date and the estimated year of final retirement. These parameters directly affect the depreciation rate calculations, therefore, informed judgment should be used in their selection.

In this proceeding, as well as the majority of utility regulatory rate case proceedings throughout the U.S. and Canada, the Iowa Curves are the general survivor curves utilized to describe the mortality characteristics of a group of property. There are four types of Iowa Curves: right-moded, left-moded, symmetrical-moded, and origin-moded. Each type describes where the greatest frequency of retirements occur relative to the ASL.

A survivor curve consists of an ASL and Iowa Curve type combination. For example, when describing property with a 50-year ASL that has mortality characteristics of the R2 Iowa Curve, the survivor curve would simply be notated as "50-R2." I present the 50-R2 survivor curve in Figure 1.

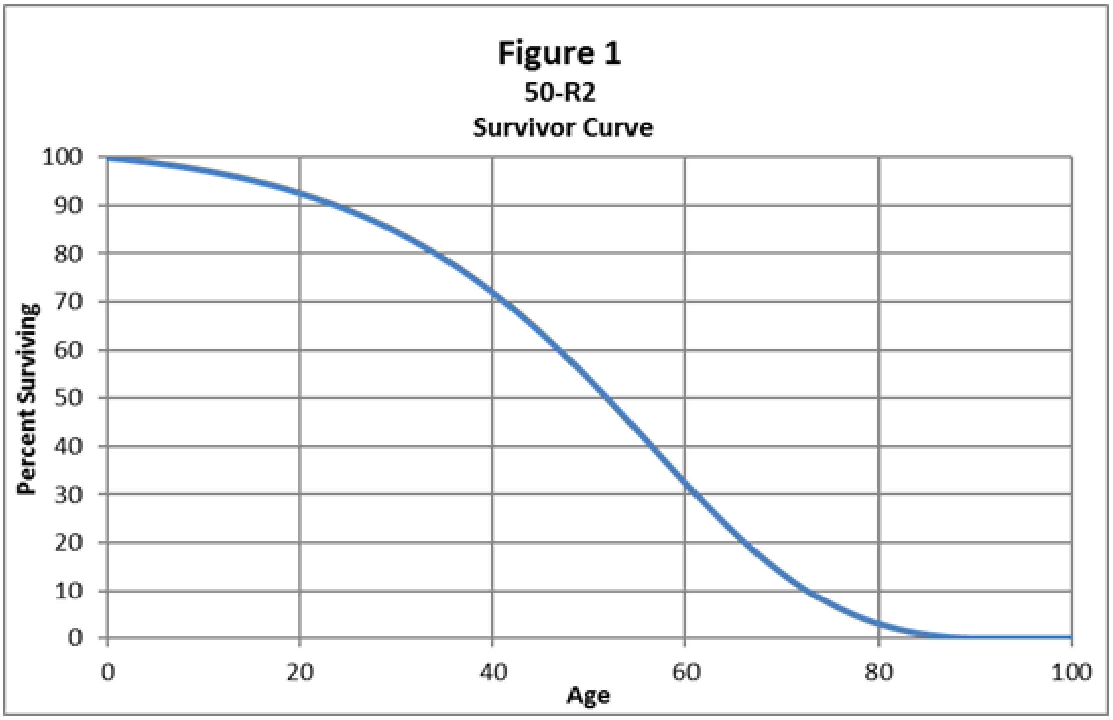

Figure 1
50-R2
Survivor Curve

Q. PLEASE DESCRIBE THE ACTUARIAL LIFE ANALYSIS THAT IS PERFORMED TO EVALUATE HISTORICAL ASSET RETIREMENT DATA.

A. I will first provide the description of actuarial life analysis (retirement rate method) that is contained in the National Association of Regulatory Utility Commissioners' ("NARUC") Public Utility Depreciation Practices Manual ("NARUC Manual"):

> Actuarial analysis is the process of using statistics and probability to describe the retirement history of property. The process may be used as a basis for estimating the probable future life characteristics of a group of property.
>
> Actuarial analysis requires information in greater detail than do other life analysis models (e.g., turnover, simulation) and, as a result, may be impractical to implement for certain accounts (see Chapter VII). However, for accounts for which application of actuarial analysis is practical; **it is a powerful analytical tool and, therefore, is generally considered the preferred approach**.
>
> Actuarial analysis objectively measures how the company has retired its investment. The analyst must then judge whether this historical view

> depicts the future life of the property in service. The analyst takes into consideration various factors, such as changes in technology, services provided, or, capital budgets.
>
> (NARUC Public Utility Depreciation Practices Manual, 1996, Page 111, Emphasis Added).

As explained by the NARUC Manual, when the required data exists, a database that contains the year of installation and the year of retirements for each vintage of property, actuarial life analysis is the preferred method of determining the life, and thus, retirement characteristics of a group of property. In this type of analysis, there are three major steps. The first step is to gather and use available aged data from the Company's continuing plant records to create an observed life table. The observed life table provides the percent surviving for each age interval of property.

The second step is to conduct a fitting analysis to match the actual survivor data from the observed life table to a standard set of mortality or survivor curves. Typically, the observed life table data is matched to Iowa Curves. The fitting process is a mathematical fitting process, which minimizes the Sum of Squared Differences ("SSD") between the actual data and the Iowa Curves.

The third step is to select the best fitting curve while using informed judgment to determine the curve that best represents the property being studied. This includes the use of a visual matching process. Although the mathematical fitting process provides a curve that is theoretically possible, the visual matching process will allow the trained depreciation professional to use informed judgment in the determination of the best fitting survivor curve.

Q. PLEASE PROVIDE FURTHER EXPLANATION OF THE SSD STATISTICAL MEASUREMENT.

A. In the Actuarial Life Analysis section of the NARUC Manual, it describes SSD as follows:

> Generally, the goodness of fit criterion is the least sum of squared deviations. The difference between the observed and projected data is calculated for each data point in the observed data. This difference is squared, and the resulting amounts are summed to provide a single statistic that represents the quality of the fit between the observed and projected curves.
>
> The difference between the observed and projected data points is squared for two reasons: (1) the importance of large differences is increased, and (2) the result is a positive number, hence the squared differences can be summed to generate a measure of the total absolute difference between the two curves. The curves with the least sum of squared deviations are considered the best fits.
>
> (NARUC, Public Utility Depreciation Practices Manual, 1996, Pages 124-125).

IV. <u>ASSESSMENT OF PEPCO'S DEPRECIATION STUDY</u>

Q. HAS PEPCO PROPOSED NEW DEPRECIATION RATES IN THIS PROCEEDING?

A. Yes. Pepco retained Mr. Ned Allis, of Gannett Fleming, to conduct a depreciation study on Pepco's property as of December 31, 2021. As stated previously, this depreciation study has been filed as Exhibit Pepco L-(1).

Q. WHAT DEPRECIATION SYSTEM DID PEPCO UTILIZE IN THE CALCULATION OF DEPRECIATION RATES PRESENTED IN EXHIBIT PEPCO L-(1)?

A. Pepco used a depreciation system consisting of the Straight Line Method, the ALG Group Procedure and the Remaining Life Technique to calculate its proposed depreciation rates.

Q. DO PEPCO'S PROPOSED NEW DEPRECIATION RATES INCREASE DEPRECIATION EXPENSE?

A. Yes. Pepco is proposing an overall depreciation rate of 3.08%. This represents an 8.5% increase over the currently approved rate of 2.84%. This change to the depreciation rate translates to an annualized depreciation expense increase of $10.62 million based on the December 31, 2021 plant balances used in the depreciation study. I show the increase by functional group in Table 1 below.

TABLE 1

Impact of Proposed Depreciation Rates and Expense
as of December 31, 2021
($ Millions)

	Current		Proposed (DC - 2.5%)		Delta (Expense)		Delta
Group	**Amount**	**Rate**	**Amount**	**Rate**	**Amount**	**Percent**	**(Rate)**
Distribution Plant	$ 114.57	2.74%	$ 123.93	2.97%	$ 9.36	8.2%	0.23%
General Plant	$ 10.07	4.60%	$ 11.34	5.18%	$ 1.26	12.5%	0.58%
Total	**$ 124.64**	**2.84%**	**$ 135.26**	**3.08%**	**$ 10.62**	**8.5%**	**0.24%**

Source: Exhibit OPC (D)-2; OPC DR 2-22, Attachment 2

Q. WHAT ARE THE MAJOR DRIVERS TO THIS PROPOSED CHANGE IN DEPRECIATION RATES?

A. The major driver of the increase to the depreciation rates is the proposed increase to net salvage rates. For the 14 distribution accounts, Pepco has proposed to increase the net rates (make more negative) for ten accounts. Accounts 367 and 368 make up the majority of the increase, totaling $9.83 million for the two accounts combined. Pepco proposed no change to the ASLs for these accounts, but the net salvage rate for both have been increased by 10%. Account 367 would move from a -60% to a -70% net salvage rate. Account 368 would move from -40% to -50%. See Exhibit OPC (D)-2, which provides the current and proposed depreciation parameters as provided by Pepco in response to OPC DR 2-22. The increase due to the change to net salvage rates is offset slightly by longer ASLs for seven of the accounts.

For General plant, the increase is largely due to the change to the net salvage rate for Account 390 from -15% to -20%.

Q. WHAT IS YOUR ASSESSMENT OF PEPCO'S DEPRECIATION STUDY?

A. Pepco's depreciation study was conducted using a depreciation system consisting of the Straight Line Method, the ALG Procedure and the Remaining Life Technique to calculate its proposed depreciation rates. I support this Method, Procedure or Technique. It appears the calculations utilized to calculate Pepco's proposed depreciation rates were performed correctly. However, I believe Pepco has overstated its depreciation rates due to a number of factors, thus, proposing an excessive level of depreciation expense to be recovered from its customers. As I will discuss, there are a number of ASL and net salvage rate adjustments that should be made to produce more reasonable deprecation rates. I also take issue with Pepco's proposed present value method for net salvage costs.

V. BCA'S DEPRECIATION STUDY

Q. PLEASE DESCRIBE YOUR DEPRECIATION STUDY.

A. Exhibit OPC (D)-3 contains the BCA Depreciation Study. The depreciation rates calculated in this study were determined using a depreciation system that consists of the Straight Line Method, the ALG Procedure, and the Remaining Life, which is the same system used by Pepco. The BCA Depreciation Study supports OPC's proposed depreciation rates.

There are three main areas of difference between the BCA Depreciation Study and Pepco's depreciation study: (1) the ASLs for nine accounts; (2) the net salvage rate for Account 362; and (3) the use of the Handy-Whitman inflation rates to determine the present value of future net salvage costs.

The adjustments to the ASLs for nine accounts are based on an actuarial analysis (retirement rate method) on Pepco's actual property data. This is the NARUC preferred method of utility property life analysis[4] and is the same method used by Mr. Allis on behalf of Pepco.

---

[4] NARUC, Public Utility Depreciation Practices Manual, 1996, page 111.

The net salvage rate adjustment for Account 362 is based on the net salvage analysis that I have conducted based on Pepco's retirement data from 1988-2021. This is the same data set analyzed in Pepco's depreciation study. The analysis for each account is presented and the adjustment is discussed.

The inflation rates to conduct the net salvage present value analysis should be based on the Handy-Whitman indices consistent with past Commission preference. Pepco's use of a single 2.5% inflation rate for all accounts should be rejected.

The adjustments proposed in the BCA Depreciation Study result in a \$22.59 million reduction to Pepco's 2021 Depreciation Study's year depreciation expense. I recommended the Commission approve OPC's proposed depreciation rates that have been presented on page 5 of Exhibit OPC (D)-3.

A. Life Analysis

Q. PLEASE PROVIDE ADDITIONAL DETAIL ON THE PROCESS USED FOR THE LIFE ANALYSIS YOU CONDUCTED ON PEPCO'S PLANT ACCOUNTS.

A. The first step in my analysis was a thorough review of the Pepco depreciation study and of Mr. Allis' workpapers. I conducted my own actuarial analysis based on the observed life tables created by Mr. Allis for his actuarial analysis. An Excel-based model that I created utilizes accepted methodologies to test the fit of the various Iowa Curves to the actual retirement data contained in the observed life tables for the Pepco plant accounts. I then used a statistical and visual analysis to select Iowa Curves and ASLs that resulted in a better statistical fit (lower SSD) than the survivor curves being recommended by

Mr. Allis. Again, the SSD is the sum of the squared differences between the Iowa Curves and the significant data points from the observed life tables. Based on my analysis, I will recommend adjustments to the ASLs of nine accounts.

In Exhibit OPC (D)-3, for each account studied beginning on Page 8, I present four sections of information. The first section contains a description of the plant account per FERC's Uniform System of Accounts. The second section contains a discussion of the proposed adjustment. The third section contains the results of the fitting analysis. This table shows for each Iowa Curve type, the ASL that minimizes the SSD. In addition, the table contains the SSD of the Pepco and BCA proposals, as well as the currently approved curve. For each account to which an adjustment is proposed, the BCA proposal has a lower SSD, which indicates a better statistical fit than both Pepco's proposal and the currently approved curve.

The next section contains a graph that shows the actual Pepco retirement data (blue triangles), the Pepco proposed curve (green long-dashed line), the BCA proposed curve (purple dotted line), the best fit curve (orange short dash-dotted line), and the currently approved curve (red short-dashed line). The best fit curve shown on the graph is the curve determined by the statistical fitting analysis to have the lowest SSD.

Q. PLEASE DISCUSS YOUR ASL ADJUSTMENT FOR ACCOUNT 367 AS AN EXAMPLE.

A. Pages 23-25 of Exhibit OPC (D)-3 is related to Account 367. Account 367 is for underground conductors and devices. The currently approved survivor curve is the 60-R2.5, which has an SSD of 4,114. Pepco is proposing to retain the currently approved curve. However, the 60-R2.5 is no longer an appropriate fit for the data, as it diverges from the significant data points around the 30-year mark. As seen in the fitting analysis results, for all curve types, the ASL is greater than 60 years, indicating that the data supports an increase to the ASL. Additionally, for the R2.5 Iowa Curve type, an ASL of 74 years is the best fit to the data. This also indicates that an increase to the ASL is necessary, however, it would not be prudent to increase the ASL by 14 years. A more gradual movement should be employed. Therefore, my recommendation is the 67-R2.5, which has a much lower SSD of 848 compared to the 60-R2.5. The 67-R2.5 is a much better fit to the actual retirement data, therefore, it will produce a more reasonable deprecation rate for this account.

In Exhibit OPC (D)-3, I provide similar discussions for all of the proposed adjustments.

Q. DO THE SURVIVOR CURVES THAT YOU ARE RECOMMENDING PRODUCE A BETTER FIT TO PEPCO'S DATA THAN THOSE BEING RECOMMENDED BY MR. ALLIS?

A. Yes. For each of the nine accounts where I am proposing a survivor curve that differs from Mr. Allis' recommendation, the SSD is lower. That is, all of my recommendations result in survivor curves that mathematically and statistically fit Pepco's data better than those recommended by Mr. Allis. The SSDs of my recommendations compared to the recommendations of Mr. Allis are shown in Table 2. For each account, the SSD of the OPC proposal is lower than the Pepco proposal.

TABLE 2

Goodness of Fit Statistics

	Pepco		OPC		Delta	
Account	**Curve**	**SSD**	**Curve**	**SSD**	**Curve**	**SSD**
362	50-R2.5	3,495	53-R2	746	3	(2,749)
364	55-R2	10,050	60-R2.5	3,419	5	(6,631)
365	50-R2	1,489	54-R2	495	4	(994)
366	70-R3	5,870	75-R3.5	1,998	5	(3,872)

Source: Exhibit OPC (D) - 3

Q. WHY IS IT IMPORTANT FOR THE SURVIVOR CURVES TO BE A BETTER FIT TO THE ACTUAL RETIREMENT DATA?

A. By selecting a survivor curve that better fits the actual retirement data, a more accurate depreciation rate can be calculated. The actual retirement data is not biased or swayed by forecasts or company personnel opinions. The survivor curve adjustments that I have proposed better reflect Pepco's actual data, resulting in more reasonable depreciation rates. The reduction to the depreciation rates for these nine accounts is necessary because these accounts exhibit ASLs greater than those being proposed by Pepco. The depreciation rates proposed by Pepco would depreciate the assets in these accounts too quickly, which is a burden on current customers.

B. Net Salvage Analysis

Q. PLEASE DISCUSS THE PROCESS USED FOR THE NET SALVAGE YOU CONDUCTED ON PEPCO'S PLANT ACCOUNTS.

A. The net salvage analysis that I have conducted is based on Pepco's retirement data from 1988-2021. This is the same dataset analyzed in Pepco's depreciation study. The analysis for each account is presented in the BCA Depreciation Study and the adjustments are discussed on Pages 62-78. For each account I present the annual retirements, cost of removal, gross salvage and net salvage, net salvage rates, the rolling 3-year, 5-year, and 10-year net salvage rates, as well as the overall average of the 34 years of retirement history. I have analyzed the same 19 accounts and am proposing adjustments to just a single account, Account 362. In general, Pepco's proposed net salvage rates are reasonable and supported by the data.

Q. PLEASE DISCUSS YOUR NET SALVAGE RATE ADJUSTMENT FOR ACCOUNT 362.

A. The currently approved net salvage rate is -30%. Pepco proposes to retain this net salvage rate. The overall average rate is -31%. Over the past 34 years, there has been approximately $51.7 million of retirements, and there is approximately $635.8 million currently in-service in this account. The retirement history reflects approximately 8% of the total account balance. Over the past 10 years, the net salvage rate has never been more negative than -30%. In fact, 8 out of the 10 previous years have shown net salvage rates between -18% and +88%. The five most recent 10-year net salvage rates have all been between -7% and -9%. A -30% net salvage rate, as proposed by Pepco, is excessive and not supported by the recent retirement history. I recommend that the net salvage rate for this account be set at -25%, which will still provide Pepco a substantial amount of net salvage recovery for this account.

C. Net Salvage Present Value Method

Q. WHAT IS THE DC PRESENT VALUE METHOD FOR NET SALVAGE COSTS?

A. The DC Present Value Method for net salvage costs is a method that has been in use in DC and Maryland for at least 13 years. It has also been referred to as the SFAS-143 Method. This is a method of reducing the costs that current customers pay for estimated removal costs for assets that will be retired in the future.

Q. WHY DOES THE COMMISSION PREFER THE SFAS-143 METHOD?

A. It is my understanding that the Commission first approved this method for Pepco in Order No. 15710 in March 2010 in FC 1076. The Commission found that "Fairness and equity require that the Commission adopt a methodology that, to the extent possible, balances the interest of current and future ratepayers. The SFAS-143 Method accomplishes this. Pepco should not be allowed to charge current customers for future inflation, nor should Pepco be allowed to charge current customers in higher-value current dollars for a future cost of removal amount that is calculated in lower value future dollars." The DC Present Value Method recognizes that current dollars are more valuable than future dollars. The traditional method of net salvage recovery results in the same level of nominal dollars provided each year for net salvage costs, ignoring the purchasing power of those dollars.

Q. WHAT INFLATION RATES DOES THE COMMISSION PREFER TO USE FOR THE PRESENT VALUE METHOD?

A. The Commission's preference is to use updated inflation-based discount rates raised on Handy-Whitman Indices as the SFAS-143 discount rates. The Commission clearly stated this preference in its Order No. 17424 in FC 1103.

Q. WHAT ARE THE HANDY-WHITMAN INDICES?

A. The Handy-Whitman Index is a long-standing publication that provides index numbers for construction cost trends in the electric, gas, and water utility industries. Established in 1924, it serves as a valuable resource for monitoring cost fluctuations in these sectors. The index is prepared by Whitman, Requardt and Associates, LLP and covers various aspects of construction, including building, electric, gas, and water utility costs. These index numbers are based on a percentage ratio between the cost of an item at a specific time and its cost at a base period, allowing for insights into cost trends over time and helping utilities, regulatory bodies, engineers, and other stakeholders make informed decisions. The indices track cost trends by FERC account, with 1973 being the base year. These indices are used to create FERC account specific inflation rates for the most-recent 20-year period.

Q. WHAT INFLATION RATE DID PEPCO USE?

A. Rather than use a distinct inflation rate for each FERC account based on the Handy-Whitman Indices, Pepco chose to use a uniform 2.5% inflation rate for all accounts, which is on historical and future growth of the CPI.

Q. DO YOU AGREE THAT A UNIFORM 2.5% INFLATION RATE SHOULD BE USED TO DISCOUNT ALL FUTURE NET SALVAGE COSTS?

A. No. This issue has been brought before the Commissions several times in Pepco's rate cases.[5] The Commission prefers to use inflation rates that are based on the Handy-Whitman Index. I agree this is the better approach. A CPI based inflation rate is based on a very broad basket of goods and services. The Handy-Whitman Indices are related to specific FERC accounts, and as such, are the most appropriate basis for discounting future net salvage costs so that current customers are not paying for future inflation costs.

Q. DID PEPCO PROVIDE THE HANDY-WHITMAN INFLATION RATES?

A. Yes. Pepco provided the Handy-Whitman Inflation rates in Exhibit Pepco (L)-1. These inflation rates range from 2.75% to 5.76%.

Q. DO THE DEPRECIATION RATES BEING PROPOSED BY OPC DISCOUNT FUTURE NET SALVAGE COSTS USING THE HANDY-WHITMAN INDICES.

A. Yes. The depreciation rates being proposed by OPC use the Handy-Whitman Index to determine the discounted level of net salvage costs to include in the deprecation rates.

---

[5] FC 1076, Order No. 15710, page 82; FC 1103, Order No. 17424, page 137; and FC 1139, Order No. 18846, page 108.

VI. <u>OPC'S PROPOSED DEPRECIATION RATES</u>

Q. HAVE YOU CALCULATED PEPCO'S DEPRECIATION RATES INCLUDING ALL OF YOUR PROPOSED ADJUSTMENTS TO THE SERVICE LIVES, NET SALVAGE RATE, AND NET SALVAGE INFLATION RATES?

A. Yes. OPC's proposed depreciation rates are presented on Page 5 of Exhibit OPC (D)-3.

Q. WHAT IS THE IMPACT OF OPC'S PROPOSED ADJUSTMENTS ON DEPRECIATION RATES AND EXPENSE AS OF DECEMBER 31, 2021?

A. Page 142 of Exhibit OPC (D)-3 shows that OPC's adjusted overall depreciation rate is 2.56%, compared to 3.08% as proposed by Pepco. When applied to the December 31, 2021 plant balances, this would reduce depreciation expense by $22.59 million. Table 3 below summarizes these results.

TABLE 3

Impact of OPC's Proposed Depreciation Rates and Expense
as of December 31, 2021
($ Millions)

	Pepco		OPC		Delta (Expense)		Delta
Group	**Amount**	**Rate**	**Amount**	**Rate**	**Amount**	**Percent**	**(Rate)**

General Plant	$ 11.34	5.18%	$ 11.28	5.16%	$ (0.06)	-0.5%	-0.02%
Total	**$ 135.26**	**3.08%**	**$ 112.68**	**2.56%**	**$ (22.59)**	**-16.7%**	**-0.52%**

Source: Exhibit OPC (D) - 3, Table 2

Q. HOW DOES OPC'S DEPRECIATION RATES AFFECT THE DEPRECIATION EXPENSE IN THE TRADITIONAL TEST YEAR?

A. In Exhibit OPC (D)-4, I calculate a decrease to traditional test year depreciation expense of $13.03 million, compared to an increase of $11.49 million proposed by Pepco. This is a $24.52 million reduction to the overall depreciation expense proposed by Pepco. Table 4 below summarizes these results.

TABLE 4

OPC's Proposed Depreciation Rates Impact to Traditional Test Year Depreciation Expense ($ Millions)

Group	Pepco Increase	OPC Increase	Delta
Distribution Plant	$ 10.10	$ (14.37)	$ (24.46)

Total	**$ 11.49**	**$ (13.03)**	**$ (24.52)**

Source: Exhibit OPC (D) - 4

Q. HOW DOES OPC'S DEPRECIATION RATES AFFECT THE DEPRECIATION EXPENSE IN THE MULTI-YEAR TEST PERIOD?

A. In Exhibit OPC (D)-5, I show that OPC's proposed depreciation rates would reduce the total depreciation expense in 2024, 2025, and 2026 by $26.37 million, $28.25 million, and $29.87 million, respectively**.** Table 5 summarized the impacts by year.

TABLE 5

Source: Exhibit OPC (D) - 5

VII. CONCLUSION

Q. MR. ANDREWS, WILL YOU PLEASE SUMMARIZE YOUR CONCLUSIONS AND RECOMMENDATIONS?

A. Yes. My conclusions and recommendations are as follows:

1. Pepco's proposed depreciation rates are excessive and burden its ratepayers with excessive depreciation expense. As proposed, Pepco's depreciation rates would be an 8.5% increase over the currently approved depreciation rates.

2. The ASLs that Pepco, through its witness, Mr. Allis, is recommending for nine plant accounts should be lengthened. Statistical fitting methods indicate that survivor curves with longer ASLs fit Pepco's historic retirement data better than what is being proposed by Mr. Allis.

3. Pepco's proposed -30% net salvage rate for Account 362 is not supported by the most recent 10 years of retirement history. -30% includes an excessive amount of net salvage accruals for Account 362. A more reasonable net salvage rate for Account 362 is -25%.

4. Pepco's proposal to use a uniform 2.5% inflation rate based on the CPI in order to discount future net salvage costs using the DC Present Value Method should be rejected. The Handy-Whitman inflation rates specific to each FERC accounts should be utilized instead.

5. The Commission should reject Pepco's depreciation rates that have been presented in Exhibit Pepco (L)-1, as they produce an excessive level of depreciation expense and burden Pepco's ratepayers.

6. The Commission should approve OPC's proposed depreciation rates that have been presented in Exhibit OPC (D)-3.

7. OPC's proposed depreciation rates would reduce the traditional test year's depreciation expense by $24.52 million.

8. OPC's proposed depreciation rates would reduce the multi-year test period depreciation expense by $26.37 million, $28.25 million, and $29.87 million in 2024, 2025, and 2026, respectively.

Q. DOES THIS CONCLUDE YOUR DIRECT TESTIMONY?

A. Yes, it does.

Qualifications of Brian C. Andrews

Q PLEASE STATE YOUR NAME AND BUSINESS ADDRESS.

A Brian C. Andrews. My business address is 16690 Swingley Ridge Road, Suite 140, Chesterfield, MO 63017.

Q PLEASE STATE YOUR OCCUPATION.

A I am a consultant in the field of public utility regulation and a Principal with the firm of Brubaker & Associates, Inc. ("BAI"), energy, economic and regulatory consultants.

Q PLEASE STATE YOUR EDUCATIONAL BACKGROUND AND PROFESSIONAL EMPLOYMENT EXPERIENCE.

A I received a Bachelor of Science Degree in Electrical Engineering from the Washington University in St. Louis/University of Missouri - St. Louis Joint Engineering Program. I have also received a Master of Science Degree in Applied Economics from Georgia Southern University.

I have attended training seminars on multiple topics including class cost of service, depreciation, power risk analysis, production cost modeling, cost-estimation for transmission projects, transmission line routing, MISO load serving entity fundamentals and more.

I am a member and a former President of the Society of Depreciation Professionals. I have been awarded the designation of Certified Depreciation Professional ("CDP") by the Society of Depreciation Professionals. I am also a certified Engineer Intern in the State of Missouri.

As an Associate at BAI, and as a Senior Consultant, Consultant, Associate Consultant and Assistant Engineer before that, I have been involved with several regulated and competitive electric service issues. These have included book depreciation, fuel and purchased power cost, transmission planning, transmission line routing, resource planning including renewable portfolio standards compliance, electric price forecasting, class cost of service, power procurement, and rate design. This has involved use of power flow, production cost, cost of service, and various other analyses and models to address these issues, utilizing, but not limited to, various programs such as Strategist, RealTime, PSS/E, MatLab, R Studio, ArcGIS, Excel, and the United States Department of Energy/Bonneville Power Administration's Corona and Field Effects ("CAFÉ") Program. In addition, I have received extensive training on the PLEXOS Integrated Energy Model and the EnCompass Power Planning Software. I have provided testimony on many of these issues before the Public Service Commissions in Arizona, Arkansas, California, Colorado, Florida, Illinois, Indiana, Kansas, Kentucky, Louisiana, Michigan, Minnesota, Missouri, Montana, New Mexico, Oklahoma, South Carolina, Texas, and Washington DC.

BAI was formed in April 1995. BAI provides consulting services in the economic, technical, accounting, and financial aspects of public utility rates and in the acquisition of utility and energy services through RFPs and negotiations, in both regulated and unregulated markets. Our clients include large industrial and institutional customers, some utilities and, on occasion, state regulatory agencies. We also prepare special studies and reports, forecasts, surveys and siting studies, and present seminars on utility-related issues.

In general, we are engaged in energy and regulatory consulting, economic analysis and contract negotiation. In addition to our main office in St. Louis, the firm also has branch offices in Corpus Christi, Texas; Detroit, Michigan; Louisville, Kentucky and Phoenix, Arizona.

POTOMAC ELECTRIC POWER COMPANY

TABLE OF CONTENTS

Tables

Executive Summary

The contents herein contain the results of the BCA Depreciation Study conducted on behalf of the Office of the People's Counsel for the District of Columbia ("OPC") on all Potomac Electric Power Company ("Pepco") plant accounts. This study contains the depreciation rates for all plants and accounts, however, there are a number of accounts to which no adjustments have been proposed. Silence with regard to any assumption does not indicate agreement with Pepco's position. All plants and accounts have been included to provide a complete set of depreciation rates for all of Pepco's property. The depreciation rates determined as a result of this study are based on the straight line method, average life group procedure, and the remaining life technique, as well as the use of Handy-Whitman inflation rates for the DC Present Value Method.

There are three main areas of difference between this depreciation study and Pepco's 2021 depreciation study: (1) the average service lives and curve types for nine plant accounts; (2) the net salvage rate for Account 362; and (3) the present value discount rates applied to each account.

The adjustments to the average service lives for the plant accounts are based on an actuarial analysis (retirement rate method) on Pepco's actual property data. This is the National Association of Regulatory Utility Commissioners' ("NARUC") preferred method of utility property life analysis and is the same method used by Mr. Allis on behalf of Pepco.

The Account 362 net salvage rate adjustment is based on the net salvage analysis that I have conducted based on Pepco's retirement data from 1988-2021. This is the same data set analyzed in Pepco's depreciation study. The analysis for each account is presented and the adjustment to Account 362 is discussed.

The discount rates applied to each account in this depreciation study are based on the Handy-Whitman Indices utilized to create Table 4 of Pepco's 2021 Depreciation Study (Exhibit PEPCO (L)-1).

The adjustments proposed in this study result in a $22.59 million reduction to Pepco's 2021 study year depreciation expense. The calculation of the depreciation rates with these proposed adjustments are summarized in Table 1.

Life Analysis

An Excel-based model that I created utilizes accepted methodologies to test the fit of the various Iowa Curves to the actual retirement data contained in the observed life tables for Pepco's plant accounts. The data for the observed life tables were contained within Mr. Allis' depreciation study.

In the fitting process, the model determines the average service life that minimizes the sum of squared differences ("SSD") between the Iowa Curve types and the significant data points from the observed life tables for each curve type. Significant data points were determined by dividing the exposures for each vintage by the Age 0 vintage exposures. If that ratio was greater than 1%, the data point was determined to be significant. The Iowa Curve and corresponding average service life that minimizes the SSD produces the "best fit" to Pepco's actual retirement of history.

The analysis provides for each Iowa Curve type, the average service life that best fits the data by minimizing the SSD. The results of this analysis are provided for each account. After the fitting analysis was performed, I created graphs that contain Pepco's retirement data, the best fit line from the fitting analysis, the survivor curve being proposed by Pepco, and my proposed survivor curve ("BCA Proposed"), as well as the currently approved curve. The BCA Proposed survivor curve for each account is typically the curve that lies between the recommendation of Pepco (Allis) and the best fit curve. In some instances the best fit produces an unreasonable average service life; however, the historical retirement pattern should not be ignored in determining the appropriate average service life and retirement dispersion because these are key inputs in developing a fair and equitable depreciation rate. In each instance the proposed average service life and retirement dispersion that I am recommending results in a better statistical fit (lower SSD) compared to the Pepco proposed survivor curve. This life analysis was conducted on all plant accounts.

For each account studied, I present four sections of information. The first section contains a description of the plant account per the Federal Energy Regulatory Commission ("FERC") Uniform System of Accounts. The second section contains a discussion of my proposed adjustment. The third section contains the results of the fitting analysis. This table shows the average service life that minimizes the SSD for each Iowa Curve type. Additionally the table contains the SSD of the Pepco and BCA proposals, as well as the currently approved curve. For each account to which I recommended a change, the BCA proposal has a lower SSD, which indicates a better statistical fit.

The last section contains a graph that shows the actual Pepco retirement data (blue triangles), the Pepco proposed curve (green long dashed line), the BCA proposed curve (purple dotted line), the best fit curve (orange dash-dotted line), and the currently approved curve (red short dashed line). The best fit shown on the graph is the curve determined by the fitting analysis which had the lowest SSD. This curve will match the survivor curve at the top of the table in the fitting analysis section.

Account 361 - Structures and Improvements

Account Description

This account is for structures and improvements. Per the FERC Uniform System of Accounts, "This account shall include the cost in place of structures and improvements used in connection with distribution operations." This includes building station control, fencing, yard improvements and other structures for distribution plant.

Discussion

The currently approved curve is 65-R3, and Pepco is proposing no change. The best fit is the 235-O2, however, I do not recommend any change from the currently approved curve.

Account 362 - Station Equipment

Account Description

This account is for Station Equipment. Per the FERC Uniform System of Accounts, “This account shall include the cost installed of station equipment, including transformer banks, etc., which are used for the purpose of changing the characteristics of electricity in connection with its distribution.” This includes much of the equipment located within the fence at a distribution substation, including busses, conduit, control equipment, transformers, switching equipment, insulators, general station equipment, platforms, foundations, etc.

Discussion

The currently approved curve is 50-R2.5 and the best fit curve is the 62-L1.5. Pepco is proposing no change from the currently approved curve. I recommend moving closer to the best fitting curve, to a flatter dispersion and increasing the average service life to 53 years, as a slightly longer ASL is indicated from the best fit curve. The R2 curve is the best fitting R-modal curve. Thus my recommendation for this account is the 53-R2, as it is more appropriate for this account, indicated by the lower SSD of 746 versus the Pepco proposal, which has an SSD of 3,495.

Account 364 - Poles, Towers and Fixtures

Account Description

This account is for Poles, Towers, and Fixtures. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of poles, towers, and appurtenant fixtures used for supporting overhead distribution conductors and service wires." This includes the poles, towers, brackets, cross arms, foundations, pole steps, ladders, anchors, etc. required to create a pole or tower structure capable of supporting overhead distribution lines.

Discussion

For this account, the currently approved curve is 50-R2, which has an SSD of 20,721. Pepco is proposing to retain the same dispersion, but increase the ASL, resulting in the Pepco recommendation of 55-R2 with an SSD of 10,050. Although Pepco's recommendation has a significantly lower SSD than the currently approved curve, the 55-R2 curve still does not properly fit the data. My analysis demonstrates that the best fitting curve is the 85-R1.5, which has an SSD of 134. While this indicates that a longer service life is necessary, it's not feasible to increase the expected life by 35 years. Taking this information into account, my recommendation is the 60-R2.5 curve, which has a much lower SSD than both the currently approved and Pepco proposal at 3,419.

Account 365 - Overhead Conductors and Devices

Account Description

This account is for Overhead Conductors and Devices. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of overhead conductors and devices used for distribution purposes." The items contained within this account include circuit breakers, conductors, ground wires, insulators, lightning arresters, railroad and highway crossing guards, switches, the initial cost of tree trimming including permits, and other line devices.

Discussion

The currently approved curve is the 45-S2 with an SSD of 10,423. Pepco proposes to change the S2 dispersion to the R2 dispersion and increase the average service life to 50 years. The fitting analysis shows that a longer life is appropriate for this account, and the 54-R2 is the best fit for the R2 dispersion with an SSD of 495. I recommend the 54-R2 curve for this account, which fits the data better than both the currently approved curve and Pepco's proposed curve.

Account 366 - Underground Conduit

Account Description

This account is for Underground Conduit. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of underground conduit and tunnels used for housing distribution cables or wires." The items contained within this account include conduit, duct banks, excavation, foundations, lighting systems, manholes, inspections, permits, sewer connections, sumps, ventilation equipment, etc.

Discussion

The currently approved curve is the 65-R4. Pepco proposes to change to R4 dispersion to the R3 dispersion, and increase the average service life to 70 years. As seen in the fitting analysis results, for all curve types, the ASL is greater than 70 years, indicating that the data supports an increase to the average service life. While the best fit is the 228-R1 curve, which has an SSD of 12.4, I recommend the 75-R3.5 for this account. The 75-R3.5 has an SSD of 1,998, which is much lower than the SSDs of 8,277 and 5,870 for the currently approved and Pepco proposed curves, respectively.

Account 367 - Underground Conductors and Devices

Account Description

This account is for Underground Conductors and Devices. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of underground conductors and devices used for distribution purposes." The items contained within this account include, circuit breakers, armored conductors, insulators, insulating materials, splicing, fireproofing, inspections, permits, cable racking, lightning arresters, switches, and other line devices.

Discussion

The currently approved survivor curve is the 60-R2.5, which has an SSD of 4,114. Pepco is proposing to retain the currently approved curve. However, the 60-R2.5 is no longer an appropriate fit for the data, as it diverges from the significant data points around the 30 year mark. As seen in the fitting analysis results, for all curve types, the ASL is greater than 60 years, indicating that the data supports an increase to the ASL. Additionally, for the R2.5 Iowa Curve type, an ASL of 74 years is the best fit to the data. This also indicates that an increase to the ASL is necessary, however, it would not be prudent to increase the ASL by 14 years. A more gradual movement should be employed. Therefore, my recommendation is the 67-R2.5, which has a much lower SSD of 848 compared to the 60-R2.5. The 67-R2.5 is a much better fit to the actual retirement data, therefore, it will produce a more reasonable deprecation rate for this account.

Account 368 - Line Transformers

Account Description

This Account is for Line Transformers. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of overhead and underground distribution line transformers and pole type and underground voltage regulators owned by the utility, for use in transforming electricity to the voltage at which it is to be used by the customer, whether actually in service or held in reserve." This includes labor of first installation, transformer cut-out boxes, transformer lightning arresters, transformers, lines and network, capacitors, network protectors, etc.

Discussion

The currently approved curve is the 35-R1.5. Pepco proposes no change. As Mr. Allis notes in Pepco's 2021 Depreciation Study (page III-4), the outlook for the assets in this account "has not changed significantly since the previous depreciation study" and the retirements are usually due to "failure and capacity." However, the current curve diverges from the significant data for the 20 year – 40 year time frame. The fitting analysis shows that the best fit to the significant data points is the 37-R2, with an SSD of 272, which more consistently matches the data. I recommend the 37-R2, since it is a better fit to the data and is only slightly different from the current curve in ASL and dispersion.

Account 369.1 – Services - Overhead

Account Description

This account is for Services. Per the FERC Uniform System of Accounts for Account 369, "This account shall include the cost installed of overhead and underground conductors leading from a point where wires leave the last pole of the overhead system or the distribution box or manhole, or the top of the pole of the distribution line, to the point of connection with the customer's outlet or wiring. Conduit used for underground service conductors shall be included herein." The items contained within this account include brackets, cables and wires, conduit, insulators, inspection, overhead to underground connections, permits, pavement, suspension wire, service switch, and protection of street openings. This subaccount is for overhead components only.

Discussion

The currently approved curve is the 50-R1 which has an SSD of 8,091. Pepco is proposing to retain the current ASL but change the dispersion to the R0.5 curve. Pepco's proposed 50-R0.5 has an SSD of 5,646. I believe that the 50-R0.5 is appropriate for this account.

Account 369.2 – Services - Underground

Account Description

This account is for Services. Per the FERC Uniform System of Accounts for Account 369, "This account shall include the cost installed of overhead and underground conductors leading from a point where wires leave the last pole of the overhead system or the distribution box or manhole, or the top of the pole of the distribution line, to the point of connection with the customer's outlet or wiring. Conduit used for underground service conductors shall be included herein." The items contained within this account include brackets, cables and wires, conduit, insulators, inspection, overhead to underground connections, permits, pavement, suspension wire, service switch, and protection of street openings. This subaccount is for underground components only.

Discussion

The currently approved curve is the 50-S4 which has an SSD of 96,934. Pepco is proposing to increase the ASL to 55-S4, which has an SSD of 55,448. Clearly, the currently approved curve is no longer appropriate for this account, and Pepco's proposal is a significantly better match to the data. However, the fitting analysis indicates that a longer average life is necessary, so I propose to the 60-R4 for this account, which has an SSD of 22,633 and is a much better overall fit than both the currently approved and Pepco's proposed curves.

Account 369.3 – Services – Underground Cable

Account Description

This account is for Services. Per the FERC Uniform System of Accounts for Account 369, "This account shall include the cost installed of overhead and underground conductors leading from a point where wires leave the last pole of the overhead system or the distribution box or manhole, or the top of the pole of the distribution line, to the point of connection with the customer's outlet or wiring. Conduit used for underground service conductors shall be included herein." The items contained within this account include brackets, cables and wires, conduit, insulators, inspection, overhead to underground connections, permits, pavement, suspension wire, service switch, and protection of street openings. This subaccount is for underground cable.

Discussion

The currently approved curve is the 55-S1.5 which has an SSD of 17,009. Pepco is proposing to change both the service life and dispersion, recommending the 60-R2.5, which has an SSD of 5,573. I agree with Pepco's recommendation to increase the average service life and change the dispersion to an R curve. However, Pepco's proposed curve diverges from the data early on, around age 30. I propose the 65-R3 curve, which has a much lower SSD of 1,483 and more closely follows the slope and curvature of the significant data points between age 40 and age 60.

Account 370 - Meters

Account Description

This account is for meters. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of meters or devices and appurtenances thereto, for use in measuring the electricity delivered to its users, whether actually in service or held in reserve." This includes labor of first installation, alternating current, watt-hour meters, current limiting device, demand indicators, demand meters, maximum demand meters, meter fittings, connections, and shelves, meter switches and cut-outs, instrument transformers, etc.

Discussion

The currently approved curve is the 30-O1. Pepco is not proposing any change to this curve. Although the best fitting curve is the 17-O2 curve, I am not recommending a change from the currently approved curve.

Account 370.1 – Meters - AMI

Account Description

This account is for meters. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of meters or devices and appurtenances thereto, for use in measuring the electricity delivered to its users, whether actually in service or held in reserve." This includes labor of first installation, alternating current, watt-hour meters, current limiting device, demand indicators, demand meters, maximum demand meters, meter fittings, connections, and shelves, meter switches and cut-outs, instrument transformers, etc. This subaccount is for AMI meters.

Discussion

The currently approved curve is the 15-S2.5. Pepco is proposing to update the dispersion curve to 15-R4, which has an SSD of 21. I agree with Pepco's proposal and recommend the 15-R4 curve.

Account 371.1 – Installations of Customers' Premises

Account Description

This account is for Installation on Customers' Premises. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of equipment on the customer's side of a meter when the utility incurs such cost and when the utility retains title to and assumes full responsibility for maintenance and replacement of such property." This includes the cost of cable vaults, commercial lamp equipment, foundations, frequency changer sets, motor generator sets, motors, switchboards panels, and wire and cable connections.

Discussion

The currently approved curve is the 35-S2 which has an SSD of 40, 125. Pepco is proposing to lengthen the average service life and change the curve type to the 40-S1.5. This is a much better fit to the data with an SSD of 16,903. This change in service life and curve type is supported by the fitting analysis, which shows that the best fitting ASL for each curve type is greater than 49 years. I support Pepco's proposal and recommend the 40-S1.5 curve.

Account 373 - Street Lighting and Signal Systems

Account Description

This account is for street lighting and signal systems. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of equipment used wholly for Public Street and highway lighting or traffic, fire alarm, police, and other signal systems." This includes automatic control equipment, conductors, lamps, municipal inspection, lamp posts, permits, series contactors, switches, etc.

Discussion

The currently approved curve is the 35-R2.5. The fitting analysis shows that the 99-R0.5 is the best fit and that lower moded curves fit the data better. Pepco proposed the 40-S0.5, which is a better fit to the data than the currently approved curve. I recommend Pepco's proposal, the 40-S0.5 curve.

Account 396 - Power Operated Equipment

Account Description

This account is for Power Operated Equipment. Per the FERC Uniform System of Accounts, "This account shall include the cost of power operated equipment used in construction or repair work exclusive of equipment includible in other accounts. Include, also, the tools and accessories acquired for use with such equipment and the vehicle on which such equipment is mounted." This includes back filling machines, boring machines, bulldozers, cranes and hoists, diggers, engines, pile drivers, pipe cleaning machines, tractors, trenchers, and other power operated equipment.

Discussion

The currently approved curve is the 25-S3 with an SSD of 3,868; Pepco is not proposing any change to this curve. The best fitting curve is the 27-R3.5, which has an SSD of 335. I recommend the 27-R3.5 for this account, as it has a much better fit than the currently approved curve.

Account 397 - Communication Equipment

Account Description

This account is for Communication Equipment. Per the FERC Uniform System of Accounts, "This account shall include the cost installed of telephone, telegraph, and wireless equipment for general use in connection with utility operations." This includes antennae, booths, cables, distributing boards, extension cords, loading coils, operators' desks, radio transmitting and receiving sets, remote control equipment and lines, etc.

Discussion

The currently approved curve is the 20-L2.5, with an SSD of 4,551. Pepco is proposing to increase the life and change the curve type in the form of the 24-L2 curve, which has an SSD of 285. This is the second best fitting curve in the fitting analysis, with the 24-L2.5 being the best fit with an SSD of 125. Since both curves are extremely close to each other, I approve of Pepco's proposal and recommend the 24-L2 curve.

Account 397.1 - Communication Equipment - Distribution

Account Description

This account is for Communication Equipment. Per the FERC Uniform System of Accounts, “This account shall include the cost installed of telephone, telegraph, and wireless equipment for general use in connection with utility operations.” This includes antennae, booths, cables, distributing boards, extension cords, loading coils, operators’ desks, radio transmitting and receiving sets, remote control equipment and lines, etc. This subaccount is for distribution equipment.

Discussion

The currently approved curve is the 15-S2.5, with an SSD of 314. Pepco is proposing to retain the current ASL and change the curve type to the 15-R1.5 curve, which has an SSD of 15. I believe Pepco’s proposal is reasonable and recommend the 15-R1.5 curve.

Net Salvage Analysis

The D&G net salvage rate adjustments are based on the net salvage analysis that I have conducted based on Pepco's retirement data from 1988-2021. This is the same data set analyzed in Pepco's depreciation study. The analysis for each account is presented and the adjustments will be discussed. For each account, I present the annual retirements, cost of removal, gross salvage, net salvage, net salvage rates, and the rolling 3-year, 5-year, and 10-year net salvage rates. I also present the overall average of the 34 years of retirement history. I have analyzed the same 16 accounts as Mr. Allis and am proposing an adjustment to only one account, Account 362, relative to Pepco's proposals.

Account 362

The currently approved net salvage rate is -30%. Pepco proposes to retain this net salvage rate. The overall average rate is -31%. Over the past 34 years, there has been approximately $51.7 million of retirements, and there is approximately $635.8 million currently in service in this account. The retirement history reflects approximately 8% of the total account balance. Over the past 10 years, the net salvage rate has never been more negative than -30%. In fact, 8 out of the 10 previous years have shown net salvage rates between -18% and +88%. The five most recent 10 year net salvage rates have all been between -7% and -9%. A -30% net salvage rate, as proposed by Pepco, is excessive and not supported by the recent retirement history. I recommend that the net salvage rate for this account be set at -25%, which will still provide Pepco a substantial amount of net salvage recovery for this account.

Present Value Net Salvage Calculations

The detailed calculations of the discounted Net Salvage Accrual and Net Salvage Theoretical Reserve seen in Table 1 are presented below. These calculations use the Handy Whitman discount factors Mr. Allis utilized to create Table 4 in Pepco's 2021 Depreciation Study (Exhibit PEPCO (L)-1).

Account 361 - Structures and Improvements
Calculation of Present Value Based Net Salvage
DC Present Value Method - Handy Whitman Discount Rates

Year	Original Cost 12/31/2021	Estimated Future Cost of Removal %	Estimated Future Cost of Removal Amount	Average Service Life	Discounted Removal Cost 3.64%	Annual Depreciation of Removal Cost	Average Remaining Life	Increment Factor in 2021 at 3.64%	Increment in Removal Cost 2021	Total Annual Depreciation Expense	Calculated Accrued Depreciation for Cost of Removal	Calculated Accrued Accretion Factor	Calculated Accrued Accretion for Cost of Removal	Theoretical Reserve
a	b	c	d=b*-c	e	f=d/((1+0.03640)^e)	g=f/e	h	i=1/(1+0.03640)^(h-1)-1/(1+0.03640)^h	j=d*i	k=g+j	l	m	n=d*m	o=l+n
